ISOLATION, CHARACTERIZATION, AND USE
OF THE HUMAN β SUBUNIT
OF THE HIGH AFFINITY RECEPTOR
FOR IMMUNOGLOBULIN E

5

BACKGROUND OF THE INVENTION

1. Field of the Invention

10 The present invention relates to DNA segments encoding the α , β , and γ subunits of the high affinity receptor for immunoglobulin E (IgE), in particular the human β subunit. The invention further relates to a method of producing the receptor by expressing DNA encoding its α , β and γ subunits in a host cell simultaneously.

2. Related Art

15 Receptors that bind the Fc region of immunoglobulins ("Fc receptors") mediate immunoglobulin transport across membranes, stimulate a variety of cellular activities induced by antigen-antibody complexes, and possibly regulate the biosynthesis of antibodies. Three of the 20 receptors (the receptor for polymeric immunoglobulin (Mostov *et al.* (1984) *Nature* (London) 308:37-43), the Fc receptors on macrophages and lymphocytes (Ravetch *et al.* (1986) *Science* 234:718-725), and the high affinity Fc, receptor on mast cells and basophils (Kinet *et al.* (1987) *Biochemistry* 26:4605-4610; Shimizu *et al.* (1988) *Proc. Natl. Acad. Sci. USA* 85:1907-1911; Kochan *et al.* (1988) *Nucleic Acids Res.* 16:3584) share a common feature: their immunoglobulin-binding portion contains two or more immunoglobulin-like domains.

30 The high affinity IgE receptor Fc_{RI} is responsible for initiating the allergic response. Binding of allergen to receptor-bound IgE leads to cell activation and the release of mediators (such as histamine) responsible for the manifestations of allergy. This 35 receptor is a tetrameric complex $\alpha\beta\gamma_2$, which is found on the surface of mast cells and basophils. The α and β

subunits have not been detected in other hematopoietic cells although the γ chains of Fc ϵ RI are found in macrophages, NK cells and T cells where they associate with the low affinity receptor for IgG (Fc γ RIII) or with the T cell antigen receptor.

The genes for α and γ , both have been localized on human (Le Coniat, 1990) and mouse chromosome 1. (Huppi, 1988; Kinet *et al.* 1987; Kochan *et al.* 1988; Shimizu *et al.* 1988; Ra *et al.* 1989.) The gene for mouse β has been localized on mouse chromosome 19 and is believed to be a single gene (Huppi, 1989). The structures of the α gene in the rat (Tepler, 1989) and of the γ gene (Kuster, 1990), but not of the β gene have been characterized in the human.

The receptor with high affinity for IgE Fc ϵ RI is found exclusively on mast cells, basophils, Langerhans cells, and related cells. Aggregation of IgE occupied Fc ϵ RI by antigen triggers both the release of preformed mediators such as histamine and serotonin, as well as stimulation of the synthesis of leukotrienes. It is the release of these mediators that results in the allergic condition.

The most thoroughly characterized Fc ϵ RI is that of the rat basophilic leukemia (FEL) cell line. It consists of three different subunits: (1) a 40-50 Kilodalton (Kd) glycoprotein alpha chain which contains the binding site for IgE, (2) a single 33 Kd beta chain and (3) two 7-9 Kd disulfide linked gamma chains (H. Metzger *et al.*, Ann. Rev. Immunol. 4:419-470 (1986)).

Complementary DNA (cDNA) for the rat α subunit has been isolated (J.-P. Kinet *et al.*, Biochemistry 26:4605-4610 (1987)). However, previously there has been no disclosure of the isolation and characterization of the β and γ subunits nor has it been possible to express IgE-binding by transfected cells (J.-P. Kinet *et al.*, Biochemistry 26:4605-4610 (1987); A. Shimizu *et al.*, Proc. Natl. Acad. Sci. USA 85:1907-1911 (1988)).

Molecular cloning of some of the subunits in rodents and humans has permitted the reconstitution of surface

3

expressed receptor complexes by trasfection. One of the surprising findings from these studies was the differential requirement for surface expression among different species. Cotransfection of the three chains, 5 α , β and γ is required to promote efficient surface expression of the rat (Blank, 1989) or mouse receptor (Ra, 1989). By contrast, some surface expression of the human $\alpha\gamma$ complex can be achieved by cotransfected α and γ alone in fibroblasts, suggesting that β may not be necessary (Miller, 1989). This result and previous 10 inability to clone the gene for the human β subunit raised the possibility that human beta might not exist and that $\alpha\gamma$ complexes might exist naturally in human cells.

15 The high affinity IgE receptor Fc,RI is a tetrameric hetero-oligomer composed of an α chain, a β chain and two disulfide-linked γ chains (chains and subunits will be used interchangeably herein). The β chain contains four transmembrane (TM) segments and long cytoplasmic domains 20 which are thought to play an important role in intracellular signalling. It was very difficult to determine whether a human beta subunit even existed, and if so, to isolate its gene. The present invention has overcome these difficulties and surprisingly provided 25 cDNA clones for the human β subunit of Fc,RI.

The invention still further provides a method of producing the complete human Fc,RI receptor, and for inhibiting formation of the receptor or its function, by inhibiting the β subunit.

30

SUMMARY OF THE INVENTION

It is an aspect of this invention to provide nucleic acid segments encoding Fc,RI subunits.

35 It is an aspect of this invention to provide nucleic acid sequences encoding the α , β , and γ subunits of Fc,RI. In particular, this invention relates to DNA sequences. An aspect of the present invention is the

structural characterization and the sequence of the complete human β gene and cDNA. Successful cloning of the human beta was not expected and was fraught with failures. Attempts to clone the human beta by simply using a rodent beta probe to screen various cDNA libraries failed to isolate a cDNA clone encoding human beta. Only a very short fragment (153 bp) with homology to rodent beta was isolated. However because this fragment may have been a portion of a beta-like molecule such as CD20, known to be homologous to beta in that region, PCR techniques were used to clone the human beta by using the information from the rodent beta sequence. However, although the homologies between human and rodent beta were 69% in the coding region, that was not sufficient for a PCR reaction. Human beta isolated by this method also failed.

The existence of human beta was questioned because human beta was believed not necessary for expression of the alpha-gamma complex. Studies of gene transfer indicated that the transfer by transfection of the three genes for alpha, beta and gamma was necessary for the expression of the rat and mouse receptor. However, transfection of human alpha and gamma was sufficient to promote the surface expression of the human receptor in fibroblasts suggesting that the human beta was not necessary for the surface expression of the human receptor. That result raised the interesting question of the existence of human beta.

Human beta was not necessary for the function of the alpha-gamma complex. Transfection of the cytoplasmic tail of gamma is sufficient for cell activation. Several groups made the observation that the cytoplasmic domain in the gamma chain was sufficient to mediate a number of biochemical signals leading to cell activation. These signals include tyrosine kinase activation, hydrolysis of phosphoinositides, calcium mobilization, production of IL2 in T cells, degranulation of mast cells and cell killing. It was demonstrated that the cytoplasmic domains of gamma contain a motif of 10-12 amino-acid

residues responsible for cell activation. This motif is sufficient to trigger many different signals in different cells. It is transferable, and seemed to be interchangeable. Again these findings raised the question of the existence of human beta. If the gamma chain is sufficient for cell activation, perhaps there was no need for a beta.

10 The inability to clone the human beta or even to detect transcripts for human beta in human cells (by using rat or mouse probes) also raised the question of the existence of human beta.

15 Cloning required inventive methods and persistence. The 153 bp fragment used to screen further cDNA libraries did not work. However, assuming that the 153 bp could be part of human beta even though the homology was only about 70%, a 25 kb genomic clone was found. Smaller inserts were found which seemed to hybridize specifically with oligonucleotide probes corresponding with rat beta sequences. All these inserts (a total of 11 kb) were sequenced to reconstitute the different exons in the quest for those encoding human beta. Using what should be the beginning of the first exon and the end of the coding sequence in the seventh exon from the putative human beta gene, a putative cDNA human beta sequence was 20 generated by PCR (by using first strand reverse transcripts from human basophils as templates for the PCR reaction.)

25 It was demonstrated that the gene and cDNA isolated encoded human beta. The isolated gene and cDNA could correspond to a beta-like or CD20-like molecule which is homologous to rodent beta. However, the homology of 69% is not a criteria for the demonstration that these sequences encode human beta. Co-expression of alpha, beta and gamma in transfectants was preferred for the demonstration that the cDNA generated is indeed encoding human beta. However these experiments were not 30 successful for the following reasons:

6

1. Co-transfection of human alpha and gamma is sufficient for surface expression and functional reconstitution of the receptor on fibroblasts.

5 2. When human beta cDNA is co-transfected with alpha and gamma, the efficiency of transfection is not increased.

In Fig. 20 the transfection of human alpha and gamma in COS-7 cells is shown to be sufficient for expression of the alpha-gamma complex on the surface of the 10 transfectants. It also shows that human beta cannot replace rat beta in the expression of the rat IgE receptor. Therefore conditions were used where co-transfection of alpha and gamma does not work, to see if 15 human beta could promote expression of the complete complex (Fig. 20). This was done by truncation of the cytoplasmic tail of human gamma. In these conditions, co-transfection of human alpha with truncated human gamma does not result in the expression of the complex. However, co-transfection of human beta (but not of CD20) 20 with alpha and truncated gamma resulted in the expression of a functional complex capable of binding IgE. In these conditions, rat beta subunit cannot replace human beta subunit for expression of human alpha and truncated gamma subunits. This assay showed that human beta could 25 associate specifically with the two other chains. Therefore, these new results demonstrate that human beta is a part of the human IgE receptor, and not merely a CD20-like molecule. These results reveal the previously unsuspected importance of human beta.

30 In Fig. 21 transfection of alpha-gamma in KU812 cells showed very little expression of receptors. The level of expression is similar to the level obtained after transfection of beta and gamma. Therefore this level may be attributable to the endogenous alpha (for beta and 35 gamma transfection) or to the endogenous beta (for alpha and gamma transfection). By contrast the level of expression after co-transfection of the three cDNAs is very substantial.

The conclusions are:

1. In mast cells and basophils, what regulates the level of expression of the receptor may be different than in fibroblasts.

5 2. In human mast cells and basophils, receptor expression requires the presence of alpha, beta gene and gamma, whereas in transfected fibroblasts, human alpha and gamma are sufficient.

10 The human beta subunit gene spans approximately 10 kb and contains seven exons. There is a single transcription initiation site preceded by a TATA box. The first exon codes for the 5' untranslated region and a portion of the N-terminal cytoplasmic tail. Transmembrane (TM) 1 is encoded in exon 2 and 3, TM 2 in exon 3 and 4, TM 3 in exon 5 and TM 4 in exon 6. The 15 seventh and final exon encodes the end of the C-terminal cytoplasmic tail and the 3' untranslated sequence. The human β gene appears to be a single copy gene.

20 Two corresponding transcripts, detected as a doublet around 3.9 kb, are present in cells of mast cell and basophil lineage from different individuals but not in the other hematopoietic cells tested. The human β protein is homologous to rodent β . The consensus amino acid sequences for human, mouse and rat β show 69% identical residues.

25 It is a further aspect of the invention to provide polypeptides corresponding to the α , β , and γ subunits of Fc_{RI}, more particularly to the human β subunit isolated from its natural environment. This may be defined to include the amino acid sequences of the polypeptides 30 either produced by recombinant methods, or synthesized by apparatus known to those of skill in the art, or isolated and purified by protein isolation and purification methods. The polypeptides comprise the entire amino acid sequence, or selected portions thereof, for example, 35 portions (domains) of the human beta subunit that are essential for (1) assembly of the receptor; (2) cell activation, and/or (3) complexing with the alpha and gamma subunits. "Natural environment" may be defined to include the subunits in the cells in which they naturally

occur, in the form and with other types of proteins and cellular components generally in structural or functional association with the subunits.

5 It is another aspect of the invention to provide a recombinant DNA molecule comprising a vector and a DNA segment encoding the α , β , or γ subunits of Fc_{RI}.

It is a further aspect of the invention to provide a cell that contains the above-described recombinant DNA molecule.

10 It is another object of the invention to provide a method of producing polypeptides having amino acid sequences corresponding to the α , β , and γ subunits of Fc_{RI}, both in rodent and human species.

15 Analysis of the surface expression of transfected receptors in fibroblast-like cells indicates that human $\alpha\gamma$ and $\alpha\beta\gamma$ complexes are expressed with comparable efficiency. Unexpectedly, assembly rules were different in other human cells. In addition, human β interacts with human α more efficiently than does rat β . By 20 contrast, both rat and mouse β interact with their corresponding α chains much more efficiently than does human β , demonstrating a strong species specificity of the α - β interaction.

25 It is a further object of the invention to provide a method of producing a functional Fc_{RI} receptor.

In one embodiment, the present invention relates to DNA segments that code for polypeptides having amino acid sequences corresponding to the α , β , and γ subunits of Fc_{RI}.

30 In another embodiment, the present invention relates to polypeptides having amino acid sequences corresponding to the α , β , and γ subunits of Fc_{RI}.

35 In a further embodiment, the present invention relates to recombinant DNA molecules comprising a vector and a DNA segment that codes for a polypeptide having an amino acid sequence corresponding to the α , β or γ subunits of Fc_{RI}.

In yet another embodiment, the present invention relates to a cell that contains the above-described recombinant DNA molecule.

5 In a further embodiment, the present invention relates to a method of producing polypeptides having amino acid sequences corresponding to the α , β , and γ subunits of FCERI.

10 In another embodiment, the present invention relates to a method of producing a functional FCERI receptor comprising introducing into a host cell DNA segments encoding the α , β , and γ subunits of Fc_{RI}; and effecting expression of said DNA segments under conditions such that said receptor is formed. Expression of the receptor on the surface of cells COS-7 or CHO is achieved by the 15 present invention when the cDNA for all three subunits of FCERI are simultaneously cotransfected. This success in expression of IgE binding permits detailed analysis of the IgE-receptor interaction and thus enables the development of therapeutically effective inhibitors.

20 An aspect of the invention is to stem the cascade of allergic responses resulting from aggregation of the high affinity receptor for IgE, by inhibiting the essential participation of the human beta subunit. The beta subunit is the target to inhibit receptor aggregation 25 and/or the function of the translate signal. Such an inhibition has widespread applications for prevention and treatment of allergic diseases because the undesirable events cascading from the receptor-IgE interaction are allergen independent and arise from various cell types: 30 mast cells, basophils, Langerhans cells and the like.

35 Inhibitors of beta include chemical preparations that attack the structure or function of the chain, anti-sense nucleic acid sequences, amino acid sequences capable of binding to the beta subunit polypeptide, and monoclonal antibodies directed to the subunit.

Effective amounts of the beta subunit inhibitors will be determined after *in vitro* cell assays, assays in animal models, and clinical trials.

Effective amounts of the inhibitors will be combined with a pharmaceutically acceptable carrier. Because of the variety of cell types in which the allergic response is related to the Fc_{RI}, and because the reaction is allergen independent, route of administration may be either systemic or atopic.

5 Candidate inhibitor substances are tested by methods disclosed herein.

10 In vitro assays for inhibitor substances are provided through host cells transfected with nucleic acid sequences for encoding the human alpha, beta and gamma subunits, complexed or incubated with inhibitors. Cell activation effected by the Fc_{RI} receptor is triggered and compared in the presence versus absence of 15 inhibitors. Many assays are available.

Further objects and advantages of the present invention will be clear from the following description and examples.

BRIEF DESCRIPTION OF THE DRAWINGS

20 FIG. 1. The nucleotide sequence (SEQ ID NO:10) and predicted amino acid sequence (SEQ ID NO:11) of human Fc_{RI} alpha cDNA are shown.

25 FIG. 2. The amino acid sequence homology of rat Fc_{RI} alpha subunit (R) (SEQ ID NO:12), human Fc_{RI} alpha subunit (A) (SEQ ID NO:13), and mouse Fc_{RI} alpha subunit (M) (SEQ ID NO:14) are shown. The regions of identity between the three are boxed. The number one position corresponds to the site of the predicted mature N-terminus of each protein.

30 FIG. 3. A flow chart showing the construction of eukaryotic expression vectors which direct the synthesis of a complete biologically active Fc_{RI} alpha chain (pHAI, pHAI_I) or a soluble, secreted, biologically active Fc_{RI} alpha chain (pHASI, pHASII) is presented. The sequence shown in this Figure is also disclosed in SEQ ID 35 NO:20.

FIG. 4. A flow chart showing the construction of a prokaryotic expression vector which directs the synthesis of a soluble biologically active Fc_{RI} alpha chain (which consists of amino acid residues 26-204) is presented.

5 The sequences shown in the pEVA construct are also shown in SEQ ID NOS. 15-17; the sequences shown in the pEVHA construct are also shown in SEQ ID NOS. 18 and 19; the sequences shown in the pEVHAS construct are also shown in SEQ ID NOS. 20 and 21.

10 FIG. 5. Restriction maps for β cDNAs and strategy by which they were sequenced. The open rectangle indicates the sequence predicted to code for the β subunit; the lines indicate the 5' and 3' untranslated regions. The upper scheme shows the 1.5 kilobase (kb) 15 clone containing a Pst I cleavage site. The lower scheme shows a 2.4-kb clone containing a Clal cleavage site. The 3' region of the latter has been truncated as indicated by the slashes. Its untranslated portion was sequenced as completely as the rest of the clone.

20 Restriction sites are indicated by vertical bars: Hf, Hinfl; Hh, Hha I; Al, Alu I; Hp, HphI; Av, Ava II; Ac, Acc I; Ec, EcoRI; Hd, HindIII. The horizontal arrows show the direction and extent of sequencing by the dideoxynucleotide chain-termination method.

25 FIG. 6. (A) Nucleotide (SEQ ID NO:22) and deduced amino acid (SEQ ID NO:23) sequences of the cDNA coding for the β subunit. Beginning at the arrowhead (▼), an alternative sequence (B) was observed in six clones. The putative transmembrane domains are underlined. The 30 tryptic peptides of the β subunit, from which the amino acid sequences were determined directly, are bracketed (<>). A putative poly (A) signal near the end is underlined. (B) Continuation of the nucleotide sequence (SEQ ID NO:24) of the deleted form of β cDNA, 3' to the junction indicated in A (▼).

35 FIG. 7. Expression of cDNA coding for the β subunit. (A) Comparison of *in vivo* and *in vitro* translation products. RBL cells were grown in [³⁵S]cysteine containing medium. The detergent extract of the cells was

precipitated with mAb β (JRK) and, after vigorous washing, extracted with sample buffer and electrophoresed (lane 1). This experiment employed concentrations of detergent high enough to dissociate the receptor completely. A 5 transcript from the β cDNA was treated *in vitro* in [35 S]methionine-containing medium (lanes 2, 3, and 5).

A control incubation contained no cDNA (lane 4). The mixtures were allowed to react with monoclonal antibodies to the β subunit after a clearing immunoprecipitation. 10 The specific washed precipitates were dissolved in sample buffer and electrophoresed: lanes 2 and 4, mAb β (JRK); lane 3, mAb β (NB); lane 5, irrelevant monoclonal antibody [mAb β (LB)]. An autoradiograph of the 12.5% polyacrylamide gel on which the specimens were analyzed 15 under reducing conditions is shown. (B) Localization of one epitome to the NH₂-terminal peptide of the β subunit. A β cDNA-containing vector was digested with HhaI before transcription using T7 polymerase. The resulting mRNA was translated to generate an NH₂-terminal peptide of the 20 β subunit β (amino acid 1-21) labeled with [35 S]methionine. The mixture was allowed to react with mAb β (JRK) (lane 1) and the irrelevant mAb(LB) (lane 2). The precipitates were analyzed on a 17% gel under nonreducing conditions. 25 (C) Expression by *E. coli* of a COOH-terminal fragment of the β subunit. A Hinfl fragment, containing nucleotides 499-787, was subcloned into an *E. coli* expression vector (Crowl *et al.* (1985) Gene 38:31-38) and extracts were prepared. The proteins were electrophoresed as in A and transferred to nitrocellulose paper. The latter was 30 allowed to react sequentially with monoclonal antibody mAb β (NB), developed with alkaline phosphatase-conjugated goat anti-mouse IgG (Fc), and developed in the usual way (Rivera *et al.* (1988) Mol. Immunol.). An enlargement of the lower half of the immunoblot is shown. Lane 1, 35 extract from transformant without insert; lane 2, extract from transformant with insert in wrong direction; lane 3, extract from transformant with insert correctly oriented. (D) Reactivity of β subunits with polyclonal antibodies induced by *E. coli*-expressed Hinfl fragments. Purified

IgE-receptor complexes were electrophoresed, transferred to nitrocellulose paper, and allowed to react with antibodies and subsequently with an appropriate alkaline phosphatase-conjugated anti-immunoglobulin antibody. Lane 5, mAb β (JRK); lane 2, mAb β (NB); lane 3, immune serum to fragment A; lane 5, immune serum to fragment B; lanes 4 and 6, preimmune sera corresponding to the immune sera in lanes 3 and 5, respectively; lanes 7 and 8, second antibody only. This gel was run without molecular weight standards.

FIG. 8. Hydropathicity plot of predicted sequence for the β subunit. The procedure and hydropathicity scale recommended by Engleman *et al.* (Engelman *et al.* (1986) *Annu. Rev. Biophys. Biophys. Chem.* 15:321-353) was used. The net hydropathicity value for the 20 amino acids for each successive "window" is plotted at the position corresponding to the 10th residue. A net free energy of >20 kcal (1 cal=4.18 J) for transfer to water suggests a transmembrane segment (Engelman *et al.* (1986) *Annu. Rev. Biophys. Biophys. Chem.* 15:321-353).

FIG. 9. Nucleotide sequence (SEQ ID NO:26) of the γ subunit of rat Fc γ RI and the amino acid sequence (SEQ ID NO:27) that it predicts. The putative transmembrane domain is underlined. Amino acid resides are numbered starting with the first residue of the mature protein. Residues 5' to residue 1 have negative numbers and include the residues encoding a putative signal peptide according to the criteria of G. von Heijne (*Nucleic Acids Res.* 14:4683-4690 (1986)). The N-terminal and C-terminal cleavage sites are indicated by an arrow. The four tryptic peptides which were covered and sequenced are bracketed. An asterisk denotes an ambiguous residue in the sequence of the first tryptic peptide.

FIG. 10. Hydropathicity plot of predicted sequences of Fc γ RI α subunit (panel A), β subunit (panel B) and γ subunit (panel C). The hydropathicity scale is according to Engelman *et al.* (*Ann. Rev. Biophys. Biophys. Chem.* 15:321-353 (1986)). The summed hydropathicity values for

the 20 amino acids in successive "windows" is plotted at the position corresponding to the tenth residue.

FIG. 11. Formation of IgE rosettes by transfected COS 7 cells and RBL cells. COS 7 cells were cotransfected with the coding portions of α , β and γ cDNAs and sensitized with mouse IgE anti-DNP before being exposed to red cells derivatized with TNP (Panel A). As a positive control, RBL cells were similarly tested for rosette formation (Panel C). The specificity of the rosetting assay was assessed by preincubating the cotransfected COS 7 cells (Panel B) and RBL cells (Panel D) with rat IgE (which lacks the anti-DNP activity) prior to the addition of the mouse anti-DNP IgE.

FIG. 12. Model of the tetrameric high affinity receptor for IgE. The polypeptides (SEQ ID NOS. 28-30) are shown in their fully processed form. The receptor is oriented such that the large extracellular portion of the α subunit is shown at the top and the remainder of the chain on the left. To the right of the α subunit (SEQ ID NO:28) is the β subunit (SEQ ID NO:29) with its four transmembrane segments and to the right of it, the dimer of γ chains (SEQ ID NO:30). Cysteines 26 and 68 and cysteines 107 and 151 in the α chain are paired as they are likely to be disulfide linked, as are the homologous cysteines in the Fc γ receptors (M. Hibbs *et al.*, J. Immunol. 140:544-550 (1988)). The putative transmembrane segments have all been shown as consisting of 21 residues and would be expected to be in an α -helical conformation. The single letter code for amino acids is used (M. Dayhoff *et al.*, in *Atlas of Protein Sequence and Structure*, Suppl. 3, ed. M. Dayhoff, 363-373, Natl. Biomed. Res. Fndtn., Washington D.C. (1978)). Every 10th residue (starting from the N-terminus) is shaded.

FIG. 13. Restriction map structure of the human β gene and exon-intron are shown. The positions of the 7 exons are depicted by boxes. The location of the start and stop codon is indicated.

FIG. 14. Nucleotide sequence (SEQ ID NO:31) of the human Fc ε RI β chain gene. The 7 exons are shown in bold.

The numbering of nucleotides is relative to the start codon. The TATAA box, translation initiation codon (ATG), termination codon (TAA) and the potential polyadenylation signals (AATAAA) are underlined. Bases which not determined with certainty are denoted as N.

5 FIG. 15. Comparison of the human β gene and rat β cDNA sequences by a dot matrix blot. The Pustell DNA Matrix of the Macvector program was used with a window of 30 nucleotides and a minimum score of 63%. The Roman 10 numerals indicated on the left correspond to the seven exons.

15 FIG. 16. Presence of transcripts in basophils are shown. Ten micrograms of total RNA from basophil enriched leukocytes and various other cells were fractionated on a denaturing agarose gel before being transferred to Nytran membranes and hybridized with human β cDNA probes (nucleotides +306 to +456 for Panel A and nucleotides -2 to + 790 in Panel C). The membrane shown in Panel A was stripped and rehybridized with a full 20 length human α cDNA probe (Panel B).

FIG. 17. Determination of the transcription initiation site.

Panel A: RNA from basophils was reverse transcribed, poly A+ tailed at both ends with terminal transferase and 25 amplified with PCR. The amplified product (cDNA) and the genomic DNA (gene) were sequenced with an identical primer and the respective sequencing reactions were run in parallel on a 8% acrylamide gel. The arrow marks the transcription start site. Panel B: RNA from basophils (lane 1) or tRNA (lane 2) were used in the primer 30 extension and the extended products analyzed on a 5% polyacrylamide urea gel in parallel with the sequencing reactions of the genomic DNA. The arrow marks the transcription start site.

35 FIG. 18. Southern blot analysis of genomic DNA obtained from five different individuals. The DNAs were subjected to distinct restriction endonuclease digestions, blotted and hybridized with the human full length cDNA for the beta subunit. The numbers on the top

indicate the different individuals while each panel corresponds to a different restriction digest. Size standards are indicated on the right.

FIG. 19. Amino acid sequence of the Fc_εRI human β subunit (SEQ ID NO:32) and alignment with rat (SEQ ID NO:33) and mouse (SEQ ID NO:34) β . Identical and non-identical amino acid residues are indicated by capital and lower case letters respectively. The identities and closely related exchanges are marked ^ in the query line while the distantly related exchanges are denoted by a dot. Non-homologous exchanges show no marking in the query line. The gaps are indicated by a hyphen. The transmembrane domains are underlined and the splice sites indicated with vertical bars.

FIG. 20. Results of FACS analysis showing IgE binding in COS-7 cells transfected with various combinations of Fc_εRI subunits.

FIG. 21. Results of FACS analysis showing IgE binding in cells of a basophil line (KU812) transfected with various combinations of Fc_εRI subunits.

DETAILED DESCRIPTION OF THE INVENTION

The present invention relates, in part, to DNA sequences which code for polypeptides corresponding to the subunits of human Fc_εRI.

More specifically, the present invention relates to DNA segments (for example, cDNA molecules) coding for polypeptides having amino acid sequences corresponding to the α , β and γ subunits of Fc_εRI. In one embodiment, the DNA segments have the sequence shown in FIG. 1, 6, 9, or 14 (SEQ ID NOS. 10, 22 and 24, 26 and 31), allelic or species variation thereof, or a unique portion of such a sequence (unique portion being defined herein as at least 15-18 bases). In another embodiment, the DNA segments encode the amino acid sequence shown in FIG. 1 (SEQ ID NO:11), 6 (SEQ ID NOS. 23 and 24), 9 (SEQ ID NO:27), or 19 (SEQ ID NOS. 32-34), or allelic or species variation

thereof, or a unique portion of such a sequence (unique portion being defined herein as at least 5-6 amino acids).

Allelic or species variations are defined as substitutions, deletions, or other alterations in the nucleotide or amino acid sequence that do not eliminate the function of the subunits as defined herein. For some uses, the nucleotide sequence may be deliberately altered to, e.g., test the effects of such alteration on the function of the beta subunit, or to produce subunits which are inactivated for certain purposes.

In another embodiment, the present invention relates to polypeptides having amino acid sequences corresponding to the α , β and γ subunits of Fc,RI. In one preferred embodiment, the polypeptides have amino acid sequences as shown in FIG. 1, 6, 9, and 19 (SEQ ID NOS. 11, 23 and 24, 27 and 32-34, respectively) or allelic or species variations thereof, or a unique portion of such sequences (unique portion being defined herein as at least 5-6 amino acids).

In another embodiment, the present invention relates to a recombinant DNA molecule comprising a vector (for example - plasmid or viral vector) and a DNA segment coding for a polypeptide corresponding to the α , β or γ subunit of Fc,RI, as described above. In a preferred embodiment, the encoding segment is present in the vector operably linked to a promoter.

In a further embodiment, the present invention relates to a cell containing the above described recombinant DNA molecule. Suitable host cells include prokaryotes (such as bacteria, including E. coli) and both lower eucaryotes (for example yeast) and higher eucaryotes (for example, mammalian cells). Introduction of the recombinant molecule into the host cell can be effected using methods known in the art.

In another embodiment, the present invention relates to a method of producing the above described polypeptides, comprising culturing the above described

host cells under conditions such that said polypeptide is produced, and isolating said polypeptide.

In a further embodiment, the present invention relates to a method of producing a functional Fc,RI receptor comprising introducing into a host cell DNA segments encoding the α , β and γ subunits of Fc,RI and effecting expression of said segments under conditions such that said receptor is formed.

The nucleic acid sequences and polypeptides according to this invention exhibit a number of utilities including but not limited to:

1. Utilizing the polypeptide or a fragment thereof as an antagonist to prevent allergic response, or as a reagent in a drug screening assay.

2. Utilizing the polypeptide as a therapeutic agent.

3. Utilizing the polypeptide for monitoring IgE levels in patients.

4. Utilizing the nucleic acid sequence to synthesize polypeptides which will be used for the above purposes.

5. Utilizing the nucleic acid sequences to synthesize cDNA sequences to construct DNA useful in diagnostic assays.

The present invention will be illustrated in further detail in the following examples. These examples are included for illustrative purposes and should not be considered to limit the present invention.

EXAMPLE 1

Isolation of cDNA Clones for the Alpha Subunit of Human Fc,RI

RNA was extracted from FUB12 cells as described by Kishi, Leukemia Research, 9, 381 (1985) by the guanidium isothiocyanate procedure of Chirgwin, et al., Biochemistry, 18, 5294 (1979) and poly(A) mRNA was isolated by oligo-dt chromatography according to the methods of Aviv, et al., P.N.A.S. U.S.A., 69, 1408 (1972).

cDNA synthesis was performed as previously described Kinet, et al., Biochemistry, 26, 2569 (1987). The resulting cDNA molecules were ligated to EcoRI linkers, digested with the restriction enzyme EcoRI, size fractioned and ligated to λgt11 EcoRI arms as set forth in Young et al., Science, 222, 778 (1983). The cDNA insert containing λgt11 DNA was packaged into bacteriophage lambda particles and amplified on Y1090. A total of 1.2x10⁶ independent cDNA clones were obtained.

The cDNA library was plated onto Y1090 on 150 mm² plates (10⁵ per plate) and transferred to nitrocellulose filters. The cDNA library filters were screened by in situ hybridization using a nick translated cDNA fragment as in Kochan, et al., Cell, 44, 689 (1986). The cDNA fragment was obtained from the rat Fc_{RI} alpha cDNA corresponding to nucleotides 119-781. Positive plaques were identified, purified and the cDNA inserts were subcloned, using standard techniques, into the pGEM vectors (Promega Biotech, Madison, Wisconsin). The cDNA insert was mapped by restriction enzyme analysis, subcloned into derivatives of pGEM and sequenced using the dideoxynucleotide method of Sanger et al., P.N.A.S., 74, 5463 (1977); following the GemSeq double strand DNA sequencing system protocol from Promega Biotech (Madison, Wisconsin). The DNA sequence was determined for both strands of the cDNA clone pLJ663 (nucleotides 1-1151); and for 300 bp of each end of clone pLJ 587 (nucleotides 658-1198). No discrepancy in DNA sequence between the two cDNA clones was observed.

The sequence for the human Fc_{RI} alpha cDNA is presented in FIG. 1 and SEQ ID NO:10. The predicted amino acid sequence for the human Fc_{RI} alpha polypeptide is shown below the nucleotide sequence and in SEQ ID NO:11, beginning with methionine at nucleotide 107-109 and ending with asparagine at nucleotide 875-877. The site of the predicted mature N-terminus was determined to be valine at nucleotide 182-184 according to the rules set forth by von Heijne, Eur. Journal of Biochem.; 137, 17; and Nucleic Acid Research, 14, 4683 (1986).

These results predict a 25 amino acid signal peptide. The rest of the cDNA sequence suggests that the human Fc_{RI} alpha chain contains about 179-224 residues with 2 homologous domains (14 out of 25 residues are identical; residues 80-104 and 163-190), a 20-residue transmembrane segment (residues 205-224) and a 33 residue cytoplasmic domain containing 8 basic amino acids. Overall, there is 47% identity between the human and rat Fc_{RI} alpha sequences, and 46% identity between the human FRI alpha and mouse FcGR alpha (FIG. 2 and SEQ ID NOs. 12-14). The greatest level of homology is within the transmembrane region where 9 amino acids surrounding the common aspartic acid residue are identical.

EXAMPLE 2

Expression of the Human Fc_{RI} Alpha Complete and Soluble Forms in Eukaryotic Cells

Using the recombinant cDNA clone for the human Fc_{RI} alpha chain, it is possible to introduce these coding sequences into an appropriate eukaryotic expression vector to direct the synthesis of large amounts of both a complete and soluble form of the alpha chain. For surface expression it may necessary that the alpha subunit be complexed with the beta or gamma subunit whereas for the eukaryotic expression of the secreted form of the alpha subunit this may not necessary. An appropriate vector for the purpose is pBC12BI which has previously been described in Cullen, (1987) Methods in Enzymology 152, Academic Press, 684. Construction of expression vectors coding for the complete alpha chain can be isolated as follows (FIG. 3): A unique BglII-SspI fragment (nucleotides 65-898) is isolated from pLJ663, the BglII end is filled in with DNA polymerase I Klenow fragment and ligated into pBC12BI which has been restricted with either HindIII-BamHI or HindIII-SmaI (the ends are made blunt by filling in with DNA polymerase I Klenow fragment). The reason for attempting two different constructions is that the former contains

a 3' intron while the latter does not. The presence or absence of introns may affect the levels of the alpha protein which are synthesized in cells transfected by these vectors. Construction of expression vectors coding for the soluble form of the alpha chain would be accomplished by introducing a termination codon at nucleotides 719-721 of the coding region in the alpha chain of the expression vectors noted above (pHAI, pHAI^I, FIG. 3). This would remove the putative transmembrane and cytoplasmic regions resulting in the synthesis of a secreted soluble form of the human alpha chain. Introduction of a termination codon is accomplished by oligonucleotide-directed site specific mutagenesis as outlined by Morinaga *et al.*, *Bio. Tech.*, 2, 636 (1984). The sequence of the oligonucleotide will be 5' AAGTACTGGCTATGATTTTTATCCCATTG 3' (SEQ ID NO:1). The resulting expression vectors are pHASI and pHASII (FIG. 3) and these will direct the synthesis of a truncated alpha protein corresponding to amino acids 1-204. Expression of this protein in eukaryotic cells will result in synthesis of a mature, IgE binding protein encompassing amino acid residues 26-204.

The expression vectors are then introduced into suitable eukaryotic cells such as CHO or COS by standard techniques such as those set forth in Cullen, (1987), *Methods in Enzymology*, Academic Press, NY 152:684, in the presence of a selectable marker such as G418 or Methotrexate resistance. The selectable marker for Methotrexate resistance has an added advantage, since the levels of expression can be amplified by introducing the cells to higher levels of drugs. The synthesis of protein is monitored by demonstrating the ability of human IgE (or rat IgE) to bind to these cells (in the case of the complete alpha chain), or in the case of the soluble form of the alpha chain, to demonstrate that the protein secreted from these cells has the ability to bind IgE in the presence or absence of the beta.

EXAMPLE 3Expression of the Human Fc_{RI} Alpha Soluble Form
in Prokaryotic Cells

Using the recombinant cDNA clone for the human Fc_{RI} alpha chain, it is possible to introduce these coding sequences into an appropriate prokaryotic expression vector to direct the synthesis of large amounts of a soluble (non-membrane bound) IgE binding polypeptide derived from the alpha chain. An appropriate vector for this purpose is pEV-1 which has been described by Crowl, *et al.*, Gene, 38, 31 (1985). Construction of an expression vector coding for a soluble alpha chain can be isolated as set forth in FIG. 4: a unique MstII-SspI fragment (nucleotides 195-898 is isolated from pLJ663, the MstII end is filled in with DNA polymerase I Klenow fragment and ligated into pEV-1 which has been restricted with EcoRI, and the ends filled in with Klenow (FIG. 4, pEVA). The N-terminus of the mature alpha chain is reconstructed by oligonucleotide directed-site specific mutagenesis. The sequence of the oligonucleotide will be -5' GAATTAATATGGTCCCTCAGAACCTAAGGTCTCCTTG 3' (SEQ ID NO:2). Introduction of this sequence into the expression vector pEVA aligns the Methionine residue of the EV-1 vector next to Valine-26 (the predicted mature N-terminus of the alpha chain) followed by amino acid residues 27-204 (pEVHA, FIG. 4). Reconstruction of the soluble form Fc_{RI} alpha is accomplished by oligonucleotide site-directed mutagenesis. The sequence of the oligonucleotide will be 5' - AAGTACTGGCTATGATTTTTATCCCATTG - 3' (SEQ ID NO:3). Introduction of this sequence into the expression vector, terminates polypeptide synthesis just prior to the start of the transmembrane region. The protein thus encoded by expression vector pEVHAS, should faithfully direct the synthesis of a soluble form of the alpha chain, corresponding to amino acid residues 26-204. This expression vector is then transformed into suitable hosts.

EXAMPLE 4Isolation and Sequence Analysis of Peptides of the Beta Subunit of Fc.RI

Since repeated attempts to sequence intact β chains were unsuccessful, peptides were isolated from tryptic digests. Electroeluted β subunits from polyacrylamide gels were prepared as described (Alcaraz *et al.* (1987) Biochemistry 26:2569-2575). Tryptic peptides were separated by high-pressure liquid chromatography and sequenced as before (Kinet *et al.* (1987) Biochemistry 26:4605-4610). A peptide (no. 1) isolated from an initial digest had the sequence (SEQ ID NO:4) Tyr-Glu-Glu-Leu-His-Val-Tyr-Ser-Pro-Ile-Tyr-Ser-Ala-Leu-Glu-Asp-Thr. The same peptide from later digests showed an additional leucine at the NH₂ terminus and an arginine at the COOH terminus. The sequences of three other peptides, each isolated in substantial yields, are indicated in a subsequent figure.

EXAMPLE 5Cloning and Sequencing of cDNA clones of the Beta Subunit of Fc.RI

RNA extracted from rat basophilic leukemia (RBL) cells by the guanidinium isothiocyanate method (Chirgwin *et al.* (1979) Biochemistry 18:5294-5299) was fractionated on an oligo(dT)-cellulose column (Maniatis *et al.* (1982) Molecular Cloning: A Laboratory Manual (Cold Spring Harbor Lab., Cold Spring Harbor, NY) and used to construct a pUC-9 and a λ gt11 library (Maniatis *et al.* (1982) Molecular Cloning: A Laboratory Manual (Cold Spring Harbor Lab., Cold Spring Harbor, NY; Young and Davies (1983) Proc. Natl. Acad. Sci. USA 80:1194-1198). The initial sequence obtained for peptide 1 was used to construct two 26-mer oligonucleotides of 32-fold degeneracy: 5' -GGIGA(A/G) TA(G/C) ACATGIA(A/G) (C/T) TC (C/T) TCATA-3' (SEQ ID NO:5) and 5' -GGICT(A/G) TA(G/C) ACATGIA(A/G) (C/T) TC(C/T) TCATA 3' (SEQ ID NO:6). A λ gt11 library constructed from mRNA of RBL

cells was screened with 1:1 mixture of these 15 oligonucleotides. Colonies were screened as in Kinet *et al.* (1987) Biochemistry 26:4605-4610, using oligonucleotides prepared on a model 380A automated DNA synthesizer (Applied Biosystems, Foster City, CA). Six positive clones gave similar restriction patterns. cDNA inserts were subcloned into pGEM-4 or pGEM-3Z and the resulting double-stranded DNA was sequenced with the GemseqRT sequencing system according to the method recommended by the supplier (Promega Biotec, Madison, WI). Twenty-mer oligonucleotides, corresponding to previously sequenced regions by this method, were used as primers to generate overlapping sequences otherwise difficult to obtain. In some instances, DNA sequencing was performed using Sequenase as recommended by the supplier (United States Biochemical, Cleveland). The clone containing the longest insert was sequenced according to the strategy shown in the upper portion of FIG. 5. The sequence predicts possible starting codons at nucleotides 46-48 and 55-57, which would yield a polypeptide of 246 or 243 residues, respectively (FIG. 6A and SEQ ID NO:22). The predicted M_r of about 27,000 is some 20% less than the apparent molecular weight of B subunits when analyzed on polyacrylamide gels (Holowka and Metzger (1982) Mol. Immunol. 19:219-227). In addition, no in-frame stop codon was apparent upstream of the start codon. To rule out the possibility that the true start codon was still further 5', the cDNA library was rescreened with a restriction fragment (nucleotides 7-474) and with a synthetic oligonucleotide probe (nucleotides 3-32). Twenty-eight additional clones were isolated and their restriction patterns were examined. Twenty were similar to the original clones. Only six additional nucleotides at the 5' end (nucleotides 1-6, FIG. 6A were identified. Early termination was found in six clones, which otherwise had the same sequence through nucleotide 375 (FIG. 6B and SEQ ID NO:24). One 2.4-kb clone had cytidine 473 substituted with an adenine. This substitution abolishes the Pst I site and creates a new

Cla I site at nucleotide 470. Also thereby, Ala-140 would become Asp-140 (FIG. 6A).

Finally, one clone extended \approx 350 base pairs (bp) in the 5' direction. The junction with the sequence shown in FIG. 6A was (SEQ ID NO:7) AATAAAACAAAAAAAAAAATG, the last two nucleotides of the newly generated ATG corresponding to nucleotides 8 and 9 of the previous sequence. It is likely that this clone simply resulted from the ligation of two independent cDNAs. Screening of the pUC-9 library revealed three clones. However, the sequence of none of these extended 5' beyond nucleotide 84.

EXAMPLE 6

RNA Transfer Blotting

RNA transfer blotting was performed under high stringency using a *Pst I* fragment probe (nucleotides 1-474). Thirty micrograms of total RNA was run on a 1% agarose gel containing 2% formaldehyde and blotted to nitrocellulose filters (Maniatis *et al.* (1982) Molecular Cloning: A Laboratory Manual (Cold Spring Harbor Lab., Cold Spring Harbor, NY). The filters were hybridized with a restriction fragment of the *B* cDNA (nucleotides 1-474) as described (Maniatis *et al.* (1982) Molecular Cloning: A Laboratory Manual (Cold Spring Harbor Lab., Cold Spring Harbor, NY) and washed with 15 mM NaCl/1.5 mM sodium citrate at 65°C. RBL cells yielded two major bands at \approx 2.7kb and 1.75kb with the upper band having about twice the intensity of the lower one. A minor band 1.2kb was also noted. Negative results were obtained with a variety of cells that do not express high-affinity IgE receptors: the rat pituitary line GH3 (American Type Culture Collection no. CCL82.1), the rat glial cell line C6 (no. CCL107), the mouse Leydig cell line 1-10 (no. CCL83), and, notably, the mouse monocytic line J774 (no. T1B67) and the rat lymphoma "NTD" (Rivera *et al.* (1988) Mol. Immunol.)

EXAMPLE 7In vitro transcription and translation

cDNAs corresponding to the β subunit and various mutated or truncated forms thereof were subcloned into either pGEM-4 or pGEM-3Z transcription vectors (Promega Biotec). The β clone containing the *Pst* I site was transcribed in vitro with T7 RNA polymerase. Unlabeled RNAs were synthesized using either SP6 or T7 polymerase as recommended by the supplier. Capping reactions were performed as reported (Contreras *et al.* (1982) Nucleic Acids Res. 10: 6353-6362). After digestion of the template with RNase-free DNase I, the RNAs were purified further by extraction with phenol/chloroform and three precipitations from ethanol. The RNA was then translated with a micrococcal nuclease-treated lysate of rabbit reticulocytes in the presence of [S^{35}] methionine as recommended by the supplier (Promega Biotec). The products of translation were diluted 1:1 with 20 mM detergent {3-[3-(cholamidopropyl)dimethylammonio]-1-propane sulfonate in borate-buffered saline (pH 8) containing 30 μ l of aprotinin per ml, 175 μ g of phenylmethyl-sulfonyl fluoride per ml, 10 μ g of leupeptin per ml, and 5 μ g of pepstatin per ml and immunoprecipitated with monoclonal antibodies as described (Rivera *et al.* (1988) Mol. Immunol.). The unfractionated translated material showed a major component at M_r 32,000 compared to the control from which the RNA had been omitted or an alternative RNA (brome mosaic virus) had been substituted.

The isolation of antibodies was as follows: *Escherichia coli* transformed with an expression vector containing the desired restriction fragments (Crowl *et al.* (1985) Gene 38:31-38; Portnoy *et al.* (1986) J. Biol. Chem. 261:14697-14703) were cultured and induced, and the fraction enriched for the recombinant protein was prepared as described (Portnoy *et al.* (1986) J. Biol. Chem. 261: 14697-14703). After separation on polyacrylamide gels in sodium dodecyl sulfate (NaDODSO₄)

the transformant-specific protein was eluted and used to immunize rabbits. Approximately 100 μ g of protein was injected in complete Freund's adjuvant; this was followed by a booster injection of 25 μ g of protein in incomplete adjuvant. The isolation and characterization of monoclonal anti- β antibodies mAb β (JRX) and mAb β (NB) (the latter, was obtained from David Halowka, Cornell University) have been described (Rivera *et al.* (1988) Mol. Immunol. 25:647-661).

10 The monoclonal anti- β antibodies mAb β (JRK) and mAb β (NB) (Rivera *et al.* (1988) Mol. Immunol.) (FIG. 7A, lanes 2 and 3) - but not an irrelevant antibody (lane 5) - precipitated radioactive material, which on polyacrylamide gels in NaDODSO₄ showed a major band at M_r 32000. This band had the identical mobility as the upper band of the doublet precipitated by mAb β (JRK) from an extract of labeled RBL cells (lane 1). Although not seen well in the reproduction, the autoradiogram showed that the material synthesized *in vitro* also contained the lower molecular weight component seen the *in vivo* synthesized β chains. The mobility of the *in vitro* synthesized protein was unaltered by reduction as has been previously observed with the β subunit. The clone containing the *Cla* I site (which lacks the first ATG codon) led to the synthesis of a protein whose mobility on gels was indistinguishable from that for the clone containing the *Pst* I site. On the other hand, an aberrant clone containing the newly generated ATG (above) induced the synthesis of a somewhat larger protein with an apparent M_r of 33,500. *In vitro* translation of a transcript coding for the NH₂-terminal 21 amino acids of the β subunit led to a product precipitable by mAb β (JRK) (FIG. 7B).

EXAMPLE 8

35 Expression of the Beta Subunit of FcRI in E. Coli

Two *Hinf*I fragments (A, nucleotides 106-498; B, nucleotides 499-787) were individually subcloned into an

E. coli expression vector, and extracts were prepared from the induced cultures. The results of one immunoblotting experiment are shown in FIG. 7C. The material extracted from the bacteria transformed with a vector containing the *HinfI* fragment B exhibited a M_r 14,000 component reactive with mAb β (NB) but not with mAb β (JRK) (FIG. 7C, lane 3). The extract from the transformants containing the more NH₂-terminal *HinfI* fragment A (residues 17-148) reacted with neither antibody (compare with above). Rabbit antibodies generated by fragment A reacted on immunoblots with purified receptors exactly at the position where the two monoclonal anti- β antibodies reacted (FIG. 7D, lanes 1-3) and quantitatively precipitated intact ¹²⁵I-labeled IgE-receptor complex from unfractionated detergent extracts of RBL cells.

EXAMPLE 9

Biosynthetic Incorporation

Biosynthetic incorporation of labeled amino acids and monosaccharides was as described (Perez-Montfort *et al.* (1983) Biochemistry 27:5722-5728). The purification and analysis on gels and by immunoblotting of the IgE-receptor complexes have also been described (Rivera *et al.* (1988) Mol. Immunol.).

By using biosynthetic incorporation of two different amino acids labeled distinguishably, their ratio in the subunits of the receptor (Table 1, right part) was determined. The ratios of four distinctive amino acids to each other was in satisfactory agreement with the ratios predicted from the β cDNA clone (Table 1, right part, columns 1-3). Because the cDNA for the β subunit predicts three potential glycosylation sites, a double-labelling experiment using [³H]mannose and [³⁵S]cysteine was also performed. Based on the relative carbohydrate data reported for the α subunit (Kaneilopoulos *et al.* (1980) J. Biol. Chem. 255:9060-9066) and correcting them on the basis of the peptide molecular weight for this

chain predicted from the cDNA, it was calculated that the α subunit contains ≈ 20 mol of mannose per mol. It was therefore possible to determine the mannose/cysteine ratio in the β subunit from the double-labeling experiment. The results showed only 0.05 mol/mol of cysteine or 0.3 mol/mol of the β subunit (Table 1, right part, column 4).

Double-labeling studies*	4.2	5.1	2.5	0.05

*The mol % of each amino acid as reported by Alcaraz et al. (1987) Biochemistry 26:2569-2575) was multiplied by 241 (the number of residues, excluding tryptophan - predicted from the cDNA. ND, not determined.

IgE-receptor complexes were purified from RBL cells incubated with a mixture of two precursors labeled with differentiable radioisotopes. The subunits were separated on a polyacrylamide gel. The gel was sectioned into 2-mm slices, extracted, and assayed for radioactivity by scintillation spectrometry. The ratio of cpm of $^{35}\text{S}/^{3}\text{H}$ was individually calculated for α , β , and γ subunits. The ratio in the α subunit is proportional to the known molar ratio of the ^{35}S -labeled and ^{3}H -labeled residues in the α subunit. Hence, the corresponding ratio in the β subunit (and the γ subunit) predicts the ratio of the same residues in the latter subunits.

EXAMPLE 10Sequence Characteristics

There is ample evidence that the cDNAs that were isolated code for the β subunit. (i) In vitro transcription of the cDNA and translation of the derived mRNA produce a protein whose apparent molecular weight on gel electrophoresis is indistinguishable from that of authentic β chains (FIG. 7A). (ii) The cDNA accurately predicts the sequence of four peptides isolated from a tryptic digest of β chains (FIG. 6A and SEQ ID NO:22) and a composition that agrees well with direct analyses and biosynthetic incorporations (Table I). (iii) Two monoclonal antibodies reactive with discrete epitopes on the β subunit (Rivera *et al.* (1988) Mol. Immunol.) precipitate the protein synthesized in vitro from the cloned cDNA (FIG. 7A), and one of them reacts with a fragment of the protein expressed in *E. coli* (FIG. 7C). (iv) Polyclonal antibodies raised against a fragment of the β subunit synthesized by *E. coli* transformants react with β chains on immunoblots (FIG. 7D) and with IgE-receptor complex in solution.

The nucleotide sequence at the 5' end of the cloned cDNA (clone 1) does not in itself define the start of the open reading frame unambiguously. There is no leader sequence and no "in frame" stop codon preceding the presumptive start codon. In addition, the molecular weight deducted from the cDNA (M_r 27,000) is substantially lower than the one observed on NaDODSO₄ gels (M_r 32,000), although the β subunit is not glycosylated. Therefore, it was possible that the start codon had been missed. Nevertheless, the aggregate data provide strong evidence that the full coding sequence for the β subunit has been recovered. (i) Extensive attempts failed to reveal cDNAs in either of two separate libraries with a more extended 5' sequence. (ii) The major species generated by 5' extension studies terminated precisely at the point at which most of our clones started. (iii) The second ATG codon at the 5' end

meets the consensus characteristics of known initiation sites (Kozak (1987) Nucleic Acids Res. 15:8125-8148). That it is preceded by a nearby 5' ATG codon is uncommon, but not rare (Kozak (1987) Nucleic Acids Res. 15: 8125-8148), and has been observed for the human α subunit (Shimizu *et al.* (1988) Proc. Natl. Acad. Sci. USA 85:1907-1911; Kochan *et al.* (1988) Nucleic Acids Res. 16:3584). (iv) As already noted, in vitro translation of an mRNA transcribed from the cDNA containing only the second ATG codon gives a polypeptide indistinguishable in length from the authentic β chains. An aberrant clone containing a start codon 48 nucleotides 5' to the presumed start codon directed the in vitro synthesis of a polypeptide with an apparent molecular weight appropriately greater than that of the β subunit. Therefore, the correspondence in apparent molecular weight between authentic β chains and the protein synthesized in vitro from clone 1 is meaningful. The RNA transfer blotting data show an mRNA of \approx 2.7Kb, precisely what would be anticipated from the cDNA that was sequenced (FIG. 6), given a poly (A) tail of \approx 200 nucleotides. In the discussion that follows it is assumed that the β chain begins with the methionine residue coded for by the second ATG and is, therefore, 243 residues long.

Only a single clone containing the *Cla* I restriction site was observed among the 37 clones analyzed. This clone likely resulted from a single base mutation during the cloning and is unlikely to represent a normally occurring mRNA. Conversely, six clones showing the deleted sequence (FIG. 6B) were observed and likely reflected an authentic species of mRNA. If translated, it would code for a M_r 14,000 protein with only a single transmembrane segment.

The sequence of the β subunit contains potential sites for N-linked glycosylation at residues 5, 151, and 154. However, past and new incorporation data give no evidence for carbohydrate in the β subunit (Perez-Montfort *et al.* (1983) Biochemistry 27:5722- 5728;

Holowka and Metzger (1982) Mol. Immunol. 19:219-227; and Table I). The sequence shows no unusual features or homology to previously reported sequences, in particular to those associated with Fc receptors or with Fc binding factors.

A hydropathicity analysis suggests that the β subunit crosses the plasma membrane four times (FIG. 8). The hydrophilic NH₂ and COOH terminus would therefore be on the same side of the membrane. Expression of fragments of the β cDNA indicate that mAb β -(NB) reacts within amino acids residues 149-243 (FIG. 7C) and that mAb β (JRK) reacts with fragment containing residues 1-21 (FIG. 7B). Because neither antibody reacts appreciably with intact cells but both react strongly with cell sonicates, the combined results are consistent with the NH₂ and COOH terminus being on the cytoplasmic side of the plasma membrane.

Earlier studies had suggested that the β chain contained a M_r 20,000 " β ," domain resistant to proteolysis while membrane bound (Holowka and Metzger (1982) Mol. Immunol. 19:219-227). This portion also contained those residues that were modified by an intrabilayer labeling reagent (Holowka and Metzger (1982) Mol. Immunol. 19:219-227; Holowka *et al.* (1981) Nature (London) 289:306-808) and became linked to the β and/or γ subunit when chemical crosslinking reagents were used (Holowka and Metzger (1982) Mol. Immunol. 19:219-227) and to the γ subunit when spontaneous disulfide linkage between the β and γ_2 subunits occurred (Kinet *et al.* (1983) Biochemistry 22:5729-5732). The remainder, " β_2 ," appeared to contain the serine residues that became phosphorylated *in situ* (Perez-Montfort *et al.*, (1983) Biochemistry 22:5733-5737; Quarto and Metzger (1986) Mol. Immunol. 23:1215-1223) but has never been positively identified as a discrete fragment. The sequence predicted by the cDNA for the β subunit suggests that part or all of either the NH₂-terminal 59 residues or the COOH-terminal 44 residues, or of both, is cleaved off to generate the β_1 fragment.

EXAMPLE 11Contransfection Experiments

5 The full-length coding sequences of the α and the β subunits were cotransfected in COS 7 cells by using a vector for transient expression. No IgE-binding sites were expressed at the surface of transfected cells.

10 Studies of the receptor with low affinity for IgE on macrophages revealed a component that could be chemically crosslinked to the IgE-binding portion and that had an apparent molecular weight similar to the β subunit of the high-affinity receptor (Finoloom and Metzger (1983) J. Immunol. 130:1489-1491). The peptides generated from this component by protease digestion appeared to differ from those released from β subunits, but it raised the 15 possibility that other Fc receptors also contained β -like subunits that had heretofore escaped detection (Rivera *et al.* (1988) Mol. Immunol.). Evidence for this from RNA transfer blot experiments conducted at high stringency is not available. In particular, J774 cells are known to 20 contain Fc γ receptors whose immunoglobulin-binding chain shows considerable homology to the α chain of the high-affinity receptor for IgE (Kinet *et al.* (1987) Biochemistry 26: 4605-4610). However, it was not possible to detect mRNA for β chains by the methods that 25 were employed. Similarly, NTD lymphoma cells gave negative results even though they have Fc γ receptors and show a low molecular weight component that reacts with mAb β (JRK) on immunoblots.

EXAMPLE 12Isolation and Sequence Analysis of Peptides of the Gamma Subunit of Fc.RI

30 Fc.RI was purified by affinity chromatography using TNP-lysine beads as described in G. Alcaraz *et al.*, Biochemistry 26:2569-2575 (1987). The eluate was applied 35 to sepharose 4B beads coupled by cyanogen bromide to monoclonal anti- β (JRK) (J. Rivera *et al.*, Mol. Immunol. 25:647-661 (1988)). After washing the beads with 2 mM

CHAPS in borate buffered saline at pH8, the bound material was eluted at 65°C with 0.1% sodium dodecyl sulfate, phosphate buffered saline, pH 6.5. The subunits from Fc_{RI} were then separated by HPLC size chromatography, the β and γ containing fractions recovered, reduced, alkylated and digested with trypsin (J.-P. Kinet *et al.*, Biochemistry 26:4605-4610 (1987)). The resulting peptides were separated by HPLC reverse phase chromatography as in J.-P. Kinet *et al.*, Biochemistry 26:4605-4610 (1987). The chromatograms from the β and γ digests were compared and the non-overlapping α peptides were sequenced (J.-P. Kinet *et al.*, Biochemistry 26: 4605-4610 (1987)).

EXAMPLE 13

15 Cloning and Sequencing of cDNA clones
of the Gamma Subunit of Fc_{RI}

Oligonucleotide probes were synthesized according to the sequences of peptide 3 (residues 41 to 47 of SEQ ID NO:27) and of peptide 4 (residues 54 to 62 of SEQ ID NO : 27) . The sequences were GA(A/G)AA(A/G)TCIGA(T/C)GCTCTCTA (SEQ ID NO:8) and AA(T/C)CA(A/G) GA(A/G)ACITA(T/C)GA(A/G)ACI(T/C)TIAA (SEQ ID NO:9). The methods used to screen the λ gt11 library, to purify, subclone and sequence the positive clones are known in the art (J.P. Kinet *et al.*, Biochemistry 26:4605-4610 (1987)). Peptide 3 and peptide 4 were also synthesized using a peptide synthesizer ABI 431A. The purity of the synthetic peptides was assessed by HPLC reverse phase chromatography, amino acid composition and mass spectroscopy. The peptides were conjugated either to ovalbumin using m -Maleimidobenzoyl-N-hydroxysuccinimide ester (F.T. Liu *et al.*, Biochemistry 18:690-697 (1979)) at a molar ratio of 5:1 or to sepharose 4B with cyanogen bromide. Rabbits were immunized with the ovalbumin-conjugated peptides, the antisera collected and the antipeptide antibodies purified by affinity chromatography using sepharose 4B

conjugated peptides. The antipeptide antibodies were tested for reactivity with the γ subunit of Fc_{RI} by Western blotting and for their ability to immunoprecipitate ¹²⁵I-IgE receptor complexes (J. Rivera *et al.*, *Mol. Immunol.* 25:647-661 (1988)). The nucleotide sequence of the γ subunit of rat Fc_{RI} (SEQ ID NO:26) obtained using the method of this invention, as well as the amino acid sequence (SEQ ID NO:27) that it predicts, are shown in FIG. 9.

In order to isolate and characterize the cDNA for the γ subunit, cDNAs for the Fc_{RI} γ subunit were isolated from a λ gt11 library prepared from rat basophilic leukemia (RBL) cells (J.P. Kinet *et al.*, *Biochemistry* 26:4605-4610 (1987)) using oligonucleotide probes. Four peptide sequences were identified in a tryptic digest of the Fc_{RI} γ subunits, and two of the peptides were used to synthesize two oligonucleotide probes (FIG. 9). The library was screened in duplicate with these two probes and overlapping plaques identified. Three discrete plaques were purified, subcloned and found to contain similar inserts of 0.6 to 0.7 kilobases (kb).

FIG. 9 shows the complete nucleotide sequence (SEQ ID NO:26) of the γ cDNA, the deduced amino acid sequence (SEQ ID NO:27) and the position in the sequence of the four original tryptic peptides. Analysis of the sequence (FIG. 10C) indicates an N-terminal hydrophobic signal peptide of 18 residues and a putative transmembrane domain separating a short extracellular portion of 5 residues from an intracytoplasmic domain. As predicted by earlier studies, the N-terminal processed γ subunit contains two cysteines, no methionine and no tryptophan residues (G. Alcaraz *et al.*, *Biochemistry* 26:2569-2575 (1987)). Compositional analysis suggested that the γ subunit might contain one histidine residue (G. Alcaraz *et al.*, *Biochemistry* 26:2569-2575 (1987)). However, biosynthetic dual labeling studies of the receptor using ³⁵S methionine and ³H histidine, clearly indicated that no trace of histidine was incorporated into the receptor-associated γ subunit. Since the open reading frame

derived from three independent clones, each predicts a histidine six residues from the C-terminal end, it is expected that the γ subunit undergoes a C-terminal processing which clips off the histidine-containing segment. Furthermore, because the peptide immediately preceding this histidine was recovered (FIG. 9 and SEQ ID NO:26), the C-terminal segment must be cleaved after Lys 63. The predicted molecular weight of the fully processed γ would therefore be 7139 Da, in close agreement with values obtained for the purified reduced γ on sodium dodecyl sulfate - urea gels (G. Alcaraz et al, Biochemistry 26:2569-2575 (1987)).

Polyclonal antipeptide antibodies to a heptamer and to a nonamer peptide of the γ subunit (FIG. 9 and SEQ ID NO:27) were prepared and tested for reactivity with IgE receptor complexes for RBL cells. Both purified antipeptide antibodies reacted in a Western blot assay with the unreduced dimer and the reduced monomer of partially purified γ subunits. In addition, both antibodies quantitatively precipitated receptor-bound ^{125}I -IgE, either from an extract of RBL cells or from a preparation of partially purified receptors. Taken together, these results leave no doubt that the cDNAs isolated according to the present invention code for the γ subunit of Fc_{RI}.

EXAMPLE 14
Expression of Receptor

In order to achieve expression of the receptor on the surface of COS 7 cells, the coding region of the α , β , and γ cDNAs were first subcloned separately into the SV 30 40 promoter-driven expression vector pSVL, prior to transfection into the COS-7 cells. The 810 bp EcoRI-Sty I restriction fragment of the α cDNA, the 965 bp EcoRI-EcoRV restriction fragment of the β cDNA and the 300 bp EcoRI-Dde I restriction fragment of the γ cDNA were subcloned separately into the Sma I site of the transient expression vector pSVL (Pharmacia, Uppsala, Sweden).

These restriction fragments individually contained the entire coding sequence of the appropriate subunit and variable portions of untranslated sequences. The only foreign sequence was the starting EcoRI recognition sequence which belonged to the initial linker. Cultured COS7 monkey kidney cells were then transfected with 40 μ l of DNA by the standard calcium phosphate precipitation technique (L. Davis *et al.*, in *Basic Methods in Molecular Biology*, ed. L. Davis, Elsevier, New York (1986)). After 48 hrs, the transfected cells (panels A and a of FIG. 11), as well as RBL cells (panels C and D of FIG. 11), were examined for surface expression of IgE binding by an IgE rosetting assay. The cells (5×10^6 cells/ml) were incubated at room temperature with (panels B and D) or without (panels A and C) μ g/ml of non-specific rat IgE for 30 min and then with 5 μ g/ml of anti-DNP-IgE (F.T. Liu *et al.*, *J. Immunol.* 124:2728-2736 (1980)). The cells were then rosetted with ox red blood cells that had been modified with 2,4,6-trinitrobenzene sulfonic acid according to a known method (M. Rittenberg *et al.*, *Proc. Soc. Exp. Biol. Med.* 132:575-581 (1969)). The results are shown in FIG. 11. FIG. 11A shows IgE-binding activity expressed by cells cotransfected with the α , β and γ subunits. Virtually all RBL cells, used as a positive control, formed rosettes (FIG. 11C). The rosettes were completely inhibited by preincubation of the cells with rat IgE (FIG. 11B and D) but not with human IgE (not shown). This coincides with the species specificity for the rat Fc_{RI} (A. Kulczycki *et al.*, *J. Exp. Med.* 139:600-616 (1974))

In order to study the requirements for surface expression of IgE-binding activity, the cells were transfected with different combinations of the cDNAs for the three subunits, as shown in Table 2.

COS-7 cells were transfected with different combinations of cDNAs for the three subunits of Fc_{RI} (FIG. 11). The rosetting assay was performed for each transfection shown in Table 2. The assessment of the mRNA by Northern blotting was performed one time only (on

2 x 10⁷ cells). Inhibitor was added to the cells in the experiments marked by an asterisk in Table 2 (50 µg/ml of non-specific rat IgE was added to the cells 30 minutes prior to the addition of the specific mouse anti-DNP IgE).

5

Cells	Transfections		Expression	
	cDNA	No.	Receptor mRNA	IgE Binding (rosettes/cells counted)
COS 7	0	9	0	0 / 12,948
	α	2	α	0 / 4,050
	αβ	2	αβ	0 / 3,504
	α	4	α	0 / 8,030
	β	1	β	0 / 2,069
	αβ	29	αβ	920 / 41,238
	αβ	4	αβ	0 / 7,542*
RBL	0	-	αβ	"100%"

*Experiments where inhibitor was added.

15 Table 2 summarizes the data derived from all the transfection experiments performed as described up to here. The success rate of the transfection experiments has improved since that data was collected so that there is now routinely achieved 5±2% expression of IgE binding when α, β and γ are simultaneously cotransfected.

20 Successful transfection was achieved for all combinations, as assessed by Northern blotting, but rosette forming cells were only detected after cotransfection of the full set of the cDNAs. These results indicate that the β and γ subunits are required for surface-expression of the IgE-binding α subunit. It is further indicated that only the fully assembled receptor reaches the plasma membrane. This phenomenon has also been observed in other systems (M. McPhaul *et al.*, Proc. Natl. Acad. Sci. USA 83:8863-8867 (1986); Y. Minami *et al.*, Proc. Natl. Acad. Sci. USA 84:2688-2692

25

(1987)) and may be generally applicable to polymeric membrane proteins.

The easy dissociability of β and γ , from α (B. Rivnay *et al.*, Biochemistry 21:6922-6927 (1982)) has raised persistent uncertainty about whether conceptually, γ_2 , and β should be considered as subunits of Fc_{RI} or as "receptor associated" proteins. (An example of the latter is the CD3 complex which associates with the antigen receptor on thymus-derived lymphocytes (H. Clevers *et al.*, Ann. Rev. Immunol. 6:629-662 (1988)). The subunit model for Fc_{RI} has been favored, for example, on the basis of the coordinate biosynthesis and catabolism of α , β and γ , (R. Quarto *et al.*, Molec. Immunol. 22: 1045-1052 (1985)). The new data on transfected cells obtained by the present invention provides the strongest evidence yet obtained that $\alpha\beta\gamma_2$ is the minimal structure for Fc_{RI}.

The present model for the tetrameric Fc_{RI} receptor is illustrated in FIG. 12 and SEQ ID NOs. 28-30. In this model each of the 589 amino acid residues of which the expressed receptor is composed is shown as a circle. In the diagram, the exterior of the cell would be at the top, the plasma membrane in which the receptor is embedded would be in the middle, and the interior of the cell towards the bottom. Each of the polypeptide chains (the α , SEQ ID NO:28, on the left, the β , SEQ ID NO:29, chain in the middle and the two γ , SEQ ID NO:30, chains on the right) contains one or more transmembrane segments.

The α chain (SEQ ID NO:28) is believed to contain two intrachain disulfide loops, and the sequences of these loops show considerable homology with immunoglobulins (J.P. Kinet *et al.*, Biochemistry 26:4605 (1987); A. Shimizu *et al.*, Proc. Natl. Acad. Sci. USA 85:1907 (1988); J. Kochan *et al.*, Nucleic Acids Res. 16:3584 (1988)). Thus, the α subunit is another member of the immunoglobulin superfamily (A. Williams *et al.*, Ann. Rev. Immunol. 6:381 (1988)). The extracellular and transmembrane segments of the α chain show considerable

homology with the immunoglobulin binding chain of Fc receptors that bind IgG (J. Ravetch *et al.*, *Science* 234:178 (1986)), but the intracellular cytoplasmic tail is quite different. The carbohydrate residues that are 5 covalently attached to the extracellular portion of the α chain are not indicated in FIG. 12. There are seven potential sites for N-linked carbohydrates (J.P. Kinet *et al.*, *Biochemistry* 26:4605 (1987); A. Shimizu *et al.*, *Proc. Natl. Acad. Sci. USA* 85:1907 (1988)), but which of 10 these that are actually used by the cell remains to be determined. Studies show that the carbohydrate is not essential for the binding of IgE by this chain (B. Hempstead *et al.*, *J. Biol. Chem.* 256:10717 (1981)).

The β chain (SEQ ID NO:29) contains four 15 transmembrane segments (J. P. Kinet *et al.*, *Proc. Natl. Acad. Sci. USA* 85:6483 (1988)) and previous studies with monoclonal antibodies (J.P. Kinet *et al.*, *Proc. Natl. Acad. Sci. USA* 85:6483 (1988); J. Rivera *et al.*, *Mol. Immunol.* 25:647 (1988)) show that the amino- and 20 carboxyltermini which are respectively 59 and 43 residues long, protrude from the cytoplasmic face of the plasma membrane. Similarly, the γ chains (SEQ ID NO:30) have an extensive intracellular extension but only very limited exposure to the exterior.

According to the general model, the putative 25 transmembrane domains of the individual subunits are predicted from their respective hydropathicity plots (see FIG. 10, wherein a net free energy of > 20 kcal/mol for transfer to water suggests a transmembrane segment or a 30 leader peptide (D. Engelman *et al.*, *Ann. Rev. Biophys. Biophys. Chem.* 15:321-353 (1986)). These plots suggest one, four and one hydrophobic domains for the α , β and each γ , respectively (i.e., seven transmembrane domains for the entire receptor). Members of a family of 35 receptors interacting with G proteins also contain seven transmembrane domains (I. Herskowitz *et al.*, *Cell* 50:995-996 (1987)). This family includes β and α adrenergic, muscarinic receptors and rhodopsin. Although no sequence homology between Fc_{RI} and these receptors is found, it

is significant that an interaction between Fc_{RI} and G proteins has been postulated to explain at least some of the biochemical pathways activated by this receptor (S. Cockcroft *et al.*, *Nature* 314:534-536 (1985)). The topology of the α and β subunits has been discussed in J.P. Kinet *et al.*, *Biochemistry* 26:4605-4610 (1987) and A. Shimizu *et al.*, *Proc. Natl. Acad. Sci. USA* 85:1907-1911 (1988), in particular, the cytoplasmic localization of the C- and N-terminal portions of the β subunit. Two pieces of evidence support the topology of the γ -dimer as shown in FIG. 12: The γ can be oxidatively iodinated on inverted vesicles but not on intact cells (D. Holowka *et al.*; *J. Biol. Chem.* 259:3720-3728 (1984)) and, *in vivo*, γ becomes phosphorylated on threonine residues (R. Quarto *et al.*, *Mol. Immunol.* 23:1215-1223 (1986)). None of the relevant residues are present in the small presumptive extracytoplasmic segment of γ but all are present on the presumptive cytoplasmic tail, i.e., two tyrosine and four threonine residues.

As a further means to examine the topology of the receptor, the putative extracellular and intracellular segments of the three subunits were analyzed for their relative content of basic residues, as suggested by G. von Heijne *Biochim. Biophys. Acta* 947:307-333 (1988). He found the ratio of basic/total residues varies as a function of the length of the segment studied, but in general was substantially higher in the non-translocated (intracellular) segments than in the translocated (extracellular) segments of membrane proteins. Table 3 below shows a good correspondence between the ratios calculated for the present model and the ratios expected on the basis of "known" membrane proteins (G. von Heijne, *Biochim. Biophys. Acta* 947:307-333 (1988)), thereby providing independent support for the topological model presented here.

TABLE 3

Ratio Lys + Arg/total in Translocated and Untranslocated Segments of Receptor Subunits

Polypeptide	No. residues	Extracellular (translocated)		No. residues	Intracellular (untranslocated)		
		Ratio			found	expected	
		found	expected				
α	179	0.13	0.11		22	0.31	
β	loop 1	17	0.06	0.04	N-term	59	
	loop 3	28	0.03	0.04	loop 2	12	
				C-term	43	0.12	
γ	5	0	0.08		36	0.22	
$\alpha\beta\gamma$	234	0.045	0.02-0.06		208	0.17	
						0.12-0.16	

10 The expected values calculated from the data in FIG. 8 of G. von Heijne, *Biochim. Biophys. Acta* 947, 307-333 (1988), in which the ratio found for the extra-membrane segments from "known" proteins has been plotted as a function of the segments' length.

15 The model clarifies several important features with respect to the organization of the subunits. The β and dimer of γ interact with each other; in detergent solutions they dissociate from the α as a unit before dissociating from each other (J. Rivera *et al.*, *Mol. Immunol.* 25:647-661 (1988)), and occasionally, β and the γ dimer are observed to be disulfide-linked to each other (J.P. Kinet, *Biochemistry* 22:5729-5732 (1983)). The 20 likeliest candidates for this bond are γ -cys7 and β -cys80 which are predicted to be topologically close. This would then require that at least the γ -cys26 residues are disulfide-linked in the γ dimer. Preliminary data on the receptor biosynthesis suggest that α and β interact with 25 each other.

30 The functional properties of Fc,RI are broadly similar to those of several Fc,R. Fc,R appears to bind to homologous segments of the immunoglobulin's Fc region (B. Helm *et al.*, *Nature* 331:180-183 (1988); A. Duncan *et al.*, *Nature* 332:563-564 (1988)), and the binding site on the receptor is found on a homologous polypeptide having immunoglobulin-like domains (J.P. Kinet *et al.*, *Biochemistry* 26:4605-4610 (1987); J. Ravetch *et al.*,

Science 234:718-725 (1986)). Both types of receptors need to be aggregated to initiate cell activation and, where studied, the latter appears to involve generation of broadly similar second messengers (H. Metzger *et al.*, 5 Ann. Rev. Immunol. 4:419-470 (1986); N. Hogg, Immunol. Today 9:185-187 (1988)). It is surprising, therefore, that whereas Fc_{RI} consists of four polypeptide chains, seven transmembrane segments and five cytoplasmic segments, Fc_{RI} appear to perform similar functions with 10 a much simpler structure, i.e., an α -like subunit alone. The extreme case is that of Fc_{RIII} which appears to lack even transmembrane and intracellular segments (P. Selvaray *et al.*, Nature 333:565-567 (1988); D. Simmons *et al.*, 15 Nature 333:568-570 (1988); T. Huizinga *et al.*, Nature 333:667-669 (1988)). It has been suggested that additional components of Fc_Y receptors may have thus far been missed. Possibly such components are even more easily lost upon solubilization of the receptors than are the β and γ subunits of FRI (J.P. Kinet *et al.*, 20 Biochemistry 24:4117-4124 (1985)). A reasonable interpretation is that such hypothetical components would be homologous to β or γ or both. The availability of genetic probes for the latter components will now permit an in-depth exploration of this possibility.

25 The success in expression of IgE binding achieved according to the present invention has important therapeutic implications. Degranulation of mast cells and basophils triggered by Fc_{RI} accounts for many of the symptoms of allergy. Given the high incidence of this 30 disorder, the discovery of a specific inhibitor of IgE binding is expected to yield enormous therapeutic benefits. The development of such an inhibitor has been hampered by the lack of a practical *in vitro* assay for the binding of human IgE to the human receptors. For 35 example, a recent assessment of IgE-derived peptides of their inhibitory capacity had to be determined by skintesting (B. Helm *et al.*, Nature 331:180-183 (1988)), a cumbersome and potentially dangerous procedure.

That the present invention achieves the expression of the transfected rodent receptor indicates that human Fc_{RI} can be similarly expressed. Alternatively, since at present only the cDNA coding for the human α subunit has been isolated (A. Shimizu *et al.*, Proc. Natl. Acad. Sci. USA 85:1907-1911 (1988); J. Kochan *et al.*, Nucl. Acids Res. 16:3584 (1988)), it is expected that it can be expressed in cotransfections with the cDNAs coding for the rodent β and γ chains.

10 A comparison between the human and rat α subunits is set forth in Table 4 below.

TABLE 4

Comparative Properties of Human and Rat Alpha Chains

Domain	Species		% Homology
	Human	Rat	
Extracellular	180	181	49
Transmembrane	21	21	67+
Intracellular	31	20	23
Total	232	222	47*
* Wt avc.			
+ Human: (amino acid residues 178-204 of SEQ ID NO:13)		WLQFFIPLLVVVILFAVDTGFLFISTQQQ	
Rat: (amino acid residues 179-205 of SEQ ID NO:12)		WLQLIFFPSLAVILFAVDTGFLWFSTHKQ	

15 It may be seen from the above Table that there is an overall homology between the human and rat alpha chains of about 47%, but an almost 70% homology in the presumed transmembrane domains. Indeed, when the transmembrane domains are examined closely, there is a stretch of 10 consecutive residues that are completely identical. This stretch of consecutive residues is underlined in Table 4.

20 Because the transmembrane segment is the region of the α chain that is most likely to interact with the β and γ chains, it was expected that the human α chain would be expressible, if transfected, along with the rat β and γ chains. This has proved to be the case as the present inventors have been able to express human IgE binding by COS cells transfected simultaneously with the human α and the rat β and γ subunits. It will be

advantageous, of course, to have permanently transfected cell lines and for such lines, one will want to utilize combinations of the IgE receptor subunits disclosed herein.

5

EXAMPLE 15The Beta Subunit of FCR Is Necessary
for Expression in Mast Cells

FIGS. 20 and 21 present the results obtained from FACS analysis (IgE binding) of cells transfected with

10

FIG. 20: represents COS-7 transfected cells.

FIG. 21: represents KU812 cells (a basophil line).

The clone of Ku812 cells used does express the mRNA for the three subunits alpha, beta and gamma but the receptor is not naturally expressed on the surface.

15

In FIG. 20, the transfection of human alpha and gamma in COS-7 cells is confirmed to be sufficient for expression of the alpha-gamma complex on the surface of the transfectants. These results also show that human beta and not rat beta associates efficiently with human alpha and that therefore, rat beta cannot replace human beta.

20

FIG. 21 illustrates that transfection of alpha-gamma in KU812 results in very little expression of receptors. The level of expression is similar to the level obtained after transfection of beta and gamma. Therefore this level may be attributable to the endogenous alpha (for beta and gamma transfection) or to the endogenous beta (for alpha and gamma transfection). By contrast the level of expression after co-transfection of the three cDNAs is very substantial.

25

From these results, it may be concluded that:

30

1. in mast cells and basophils, regulation of the level of expression of the receptor may be different than in fibroblasts.

35

2. in human mast cells and basophils, receptor expression requires the presence of alpha, beta and

gamma; whereas in transfected fibroblasts, human alpha and gamma are sufficient.

EXAMPLE 16

Isolation, Mapping and Sequencing of the Human Fc_εRI β Gene

Initial attempts to isolate human β cDNA clones were by screening a human mast cell cDNA library with full-length rat and mouse cDNA probes. These probes were radiolabeled and used to screen 7×10^5 colonies. Four clones were isolated, all of which contained a 153 bp insert with 73% homology to rat β cDNA. The sequence of this insert corresponded to a portion of β which includes the intracellular loop and the third transmembrane domain. These four identical clones are the likely result of library amplification of a single clone generated by recombinations. Two additional libraries were screened: another mast cell cDNA library and a cDNA library derived from basophil-enriched leukocytes. The latter library was also used to isolate human γ cDNA clones. A total of 107 independent cDNA clones were screened with a panel of murine probes and oligonucleotides and with the 153 bp human β probe. However no additional clones were isolated.

25 6×10^5 independent genomic clones from a human genomic leukocyte library with the radiolabeled 153 bp human probe were subsequently screened, and 10 clones with an average size insert of 25 kb were isolated. These clones all hybridized with two 20 mer-oligonucleotide probes corresponding to the beginning and the end of the rat β coding γ sequence. Four different restriction patterns could be generated from the 10 clones. However, southern blots with various oligonucleotide probes scanning different regions of the rat β coding sequence indicated that the four restricted patterns were not the product of different genes. Rather the clones showed differences in the lengths of the sequences flanking the β gene.

One clone containing a 25 kb insert was chosen for further characterization mapping and sequencing. A

restriction map shown in Fig. 13 was constructed by complete and incomplete digestion with the restriction endonucleases Hind III, Pst I, BamH I, Xba I, Sma I and Kpn I. A 3.2 kb Hind III fragment was found to hybridize with oligonucleotide probes corresponding to the start codon, and transmembrane region I and II of rat β . A 2.8 kb Sma I fragment hybridized with rat β probes of transmembrane domain III and IV and a 4.5 kb Sma I fragment with probes of the stop codon region. The 3 fragments were subcloned into pGEM 3zf (+) or (-) and sequenced in full (FIG. 14 and SEQ ID NO:31). The fragment corresponding to the 0.9kb gap between the Hind III and 2.8 kb Sma I fragments was produced by PCR and sequenced. Analysis using PCR confirmed that the two Sma I fragments were adjacent to each other.

By comparing the sequences of the human β gene and the rat β cDNA (FIG. 15) seven homologous regions which were likely localized to correspond to seven different exons.

20

EXAMPLE 17Synthesis of Human β cDNA Coding Sequence

In order to confirm the sequence of the exons and to define the intro-exon borders, human β cDNA was synthesized by reverse transcription of RNA purified from basophil-enriched leukocytes followed by an amplification of the reverse transcripts using the polymerase chain reaction (PCR) (described in Materials and Methods herein). This applied product extended from 2 nucleotides preceding the start codon to 32 nucleotides following the stop codon. The cDNA sequence was found to be identical to the corresponding sequence of the human β gene. This confirmed that the coding sequence of human β is contained in seven exons. Furthermore, the comparison of cDNA and gene sequences and the detection of consensus sequences for intron-exon borders in the human β gene allow for a precise determination of these

borders. The 5' borders of the six intervening introns invariably start with GT and the 3' borders end with AG.

EXAMPLE 18

Analysis of Human β Transcripts

5 To evaluate the length of 5' and 3' untranslated sequences, the size of human β transcripts was analyzed. RNA from basophil-enriched leukocytes obtained from different individuals were hybridized by northern blotting with the radiolabeled 153 bp human β probe (FIG. 16A) Two transcripts around 3.9 kb were found in human basophils but not in COS-7 cells. The human transcripts are substantially longer than their rodent counterparts (2.7 and 1.75 kb) (Ra. 1983, Kinet, 1988) as detected in RBL cells by crosshybridization. This longer size may 10 explain initial failures to isolate human β cDNAs from the three oligo-dT primed libraries. Similar results were obtained with a full-length cDNA probe of human β . Hybridization of the same RNAs with a human α cDNA probe 15 revealed transcripts for α of the expected size (1.1 kb) (FIG. 16B). RNA from different cell lines were also hybridized with a full length human β cDNA probe (FIG. 16C). The message for human β is only detected in the basophil line KU812 but not in U937, Daudi and Hela 20 cells. An additional band is seen in KU812 which could 25 correspond to unspliced transcripts.

With an open reading frame of 732 bp and assuming 200 bp for the poly A tail, human β transcripts should contain about 3 kb of untranslated sequences. FIG. 15 shows that most of the untranslated sequences are 30 in the seventh exon. The possibility that additional exons of 3' or 5' untranslated sequences had not yet been identified was also explored.

EXAMPLE 19A. Characterization of the (A) 5' End and of the Transcription Initiation Site

The transcription start site was determined by sequencing directly a PCR amplified product of the reverse transcribed RNA as described in "Experimental Procedures". RNA from basophil-enriched leukocytes was reverse transcribed from a primer of the human β coding sequence. Poly-A tails were added to the reverse transcripts by treatment with terminal transferase and the resulting cDNAs were amplified by PCR. Single stranded DNAs (positive strands poly dT tailed) were then produced by asymmetric PCR and directly sequenced. The cDNA sequence of the negative strand corresponding to the 5' end of the RNA is shown in FIG. 5A and is compared to the relevant sequence of the β gene. The perfect match between the two sequences ends after GGGTT. Then the cDNA sequence reproducibly shows a C, which is not present in the gene, followed by the expected poly-A tail. This additional C may correspond to the G of the cap structure and indicate the location of the start site.

Experiments of 5' extension (FIG. 17B) confirmed that there is a major start site in this area (about 11 nucleotides 3' of the position described above). It is difficult, though, to exclude the possibility that the faint bands seen below and above the major start sites correspond to minor start sites. However the presence of a TATAAA box found in the 5' sequence supports the existence of a unique start site. In addition the location of the TATAAA box (usually 25 nucleotides 5' of the start site) is more consistent with the precise localization of the start site as shown.

Indeed the TATAAA box is located between nucleotides 29 and 24 upstream of this start site as shown in FIG. 17A. Taken together the data indicate that the human β mRNA start with the sequence AACCC (see FIG. 14, SEQ ID NO:31, and FIG. 17A) and has 102 bp of 5' untranslated sequence.

B. Characterization of the 3' end

A comparison between the rat β cDNA and human β gene sequences FIG. 15) shows that the seventh exon of the β gene extends at least from nucleotides 6773 to at least 5 nucleotide 8910. But an additional 3' untranslated sequence (about 800 bp) had to be found to fully account for the 3.9 kb transcripts. To analyze whether the missing sequence was part of the seventh exon or of other undetected exons, three probes from the β gene were 10 prepared to test their reactivity with β transcripts. These transcripts hybridized in northern blots with both the Nsil-BamH1 fragment (nucleotides 8460-9250) and the BamH1-SphI fragment (nucleotides 9250-9714) but not with the fragment 3' of the SphI site. Interestingly two 15 polyadenylation signals AATAAA are found at nucleotides 9663 and 9758 (FIG. 14 and SEQ ID NO:31). Therefore this region is likely to correspond to the end of exon 7. It is likely that both polyadenylation signals could be used to create the apparent doublet of transcripts around 3.9 20 kb (see FIG. 16).

EXAMPLE 20Organization of the Human β Gene

Taken together the data presented herein indicate 25 that the human β gene contains seven exons and six introns and spans about 10 kb. Exon 1 codes for 102 bp of 5' untranslated sequence and the first 18 amino acid residues of the N-terminal cytoplasmic tail. Exon 2 encodes the remaining of the cytoplasmic tail and the first three residue of TM1. Exon 3 codes for the 30 remaining of TM1, the first extracellular loop and the first half of TM2. Exon 4 encodes the second half of TM2 and a portion of the cytoplasmic loop. Exon 5 codes for the last three residue of the cytoplasmic loop, TM3 and most of the second extracellular loop. Exon 6 codes for the 35 last two residues of the extracellular loop, TM4 and the first quarter of the C-terminal cytoplasmic tail.

Finally, exon 7 codes for the remaining of the cytoplasmic tail and the long untranslated 3' sequence.

EXAMPLE 21

The Human β Protein

5 The human β protein comprises 244 amino-acid (aa) residues and has a molecular mass of 26,532 daltons (FIG. 18). Similar to rat (243 aa) and mouse β (236 aa), human β contains four hydrophobic segment suggestive of transmembrane domains (TM) but no leader peptide. FIG. 10 shows an alignment of the human sequence (SEQ ID NO:32) with the rat (SEQ ID NO:33) and mouse (SEQ ID NO:34) sequence. The consensus sequence for β (not shown) from the three species (rat, mouse and human) shows that 91.4% of the amino-acid residues are 15 homologous while 68.7% are identical.

EXAMPLE 22

Transfection in COS-7 Cells:
Expression of Human and Hybrid Fc_{RI} Receptors

Table 5

5 Functional expression of Fc_{RI} after transfection
 of various subunit combinations

	Transfected cDNAs			% Fluorescent cells (FACS)		
				n	Mean	± SD
	Human α	-	-		10.2	
10	Human α	Human β	-		10.2	
	Human α	-	Human γ	7	10.4	± 8.7
	Human α	Human β	Human γ		78.3	± 5.0
	Human α	Rat β	Human γ		45.4	± 3.4
	Rat α	Rat β	Rat γ	8	18.0	± 17.8
15	Rat α	Human β	Rat γ		102.4	± 2.0
	Rat α	Human β	Human γ		51.8	± 1.3
	Mouse α	Mouse β	Mouse γ		48.2	± 5.6
	Mouse α	Human β	Mouse γ		61.6	± 1.2
	Mouse α	Human β	Human γ		21.5	± 0.8
20	Human α	-	Rat γ_{unc}		71.4	± 1.0
	Human α	Rat β	Rat γ_{unc}		53.2	± 2.8
	Human α	Human β	Rat γ_{unc}		77.4	± 7.9
	Rat α	Rat β	Rat γ_{unc}		29.3	± 0.8
	Rat α	Human β	Rat γ_{unc}		20.4	± 0.5

25 It was found that co-transfection of α , β , and γ cDNAs is necessary to promote expression of rat or mouse Fc_{RI} on the surface of transfected COS-7 cells. By contrast, co-transfection of human α and β cDNAs results in the surface expression of $\alpha\gamma$ complexes without apparent need for γ . With the availability of human γ cDNAs, the question was explored whether human β would influence in any way the efficiency of surface expression

30

of the human receptor complex. Table 5 shows that co-transfection of human α and γ cDNAs into COS-7 cells results in $10.4\% \pm 8.7$ of the cells being fluorescent when analyzed by FACS after binding of fluoresceinated IgE. This level of expression is not significantly modified when human β cDNA is co-transfected with human α and γ cDNAs ($8.3\% \pm 5.0$). Thus, human β does not seem to influence the level of surface expression of human Fc ϵ RI in transfected COS-7 cells. Substituting rat β or human β reduces the level of expression ($5.4\% \pm 3.4$).

The effect of substituting human β for rat β was analyzed. Co-transfection of rat α , β , γ cDNAs result in much higher level of expression ($18.0\% \pm 17.8$) than co-transfection of rat α , γ with human γ ($2.5\% \pm 2.0$) (Student's t statistic = 2.75; $p \leq 0.014$). Similarly co-transfection of mouse α , β , γ cDNAs is more efficient ($8.2\% \pm 5.6$) than co-transfection of mouse α , γ with human β ($1.6\% \pm 1.2$) (Student's t statistic: 2.91; $p \leq 0.019$). Because replacing rat γ or mouse γ with human γ does not restore expression (compare 2.4% with 1.8% , and 1.6% with 1.5%), it is likely that the problem of expression resides in the human β -rat α or human β -mouse α interaction.

It is known that truncation of the cytoplasmic tail of rat γ prevents the surface expression of human α in transfectants (Varni-Blank, 1990). The question was whether human β could complement the surface expression of human α in these conditions. It was confirmed that co-transfection of human α with truncated rat γ permit only very poor surface expression of $\alpha\gamma$ complexes ($1.4\% \pm 1.0$). When human β is co-transfected with the latter combination there is an increase of expression ($7.4\% \pm 7.3$, $n=7$). However this increase does not become significant ($p \leq 0.035$) when one aberrant point is not included in the seven experiments. The same increase is not observed when rat β is substituted for human β ($3.2\% \pm 2.8$) suggesting again that there may be specific points of interaction between human α and β . In other experiments using the truncated rat γ , it was found that

human β cannot be substituted for rat β in its interaction with rat α (compare 9.3% \pm 0.6 with 0.4% \pm 0.4; (t = 13.0; $p \leq 0.006$).

5 Taken together these data indicate that there is a tendency for human β to interact more efficiently with human α than does rat β , but the species specificity is weak. By contrast, there is a strong species specificity in the interaction between rat β and rat α or between mouse β and mouse α .

10 Human $\alpha\gamma$ complexes may be expressed on the surface of transfected cells. Moreover co-transfection of human α and γ with rat β results only 20% of the receptors being $\alpha\beta\gamma$ complexes, the remaining 80% being $\alpha\gamma$ complexes. Therefore, it is theoretically possible that $\alpha\gamma$ complexes occur naturally. However in view of the species specificity of interaction between human β and α (see above), previous results obtained from the co-transfection of human α and γ with rat β suggest the *in vivo* situation could be different.

15 20 These genetic results, of course, provides much more than an assay, as important as the latter may be. Through directed mutation it will, in addition, allow the development of further information regarding the critical binding regions. It is expected that, using this information, rational drug design will become possible. It is further expected that it will be possible to block the function of the receptor itself, i.e., it will be possible to interfere with the early biochemical signals that result from activation of the receptor.

25 30

EXAMPLE 23

Detection of a Candidate Inhibitor Substance

In still further embodiments, the present invention concerns a method for identifying new Fc_{RI} inhibitory compounds, which may be termed as "candidate substances." 35 It is contemplated that this screening technique will prove useful in general identification of any compounds that will serve the purpose of inhibiting the formation

of Fc_{RI} as measured by various cell activation assays. (Mouse Interleukin-2 ELISA kit, Alberts *et al.*, pp. 179-180, Adamczewski *et al.* (in press), Barones *et al.*, 1991).

5 Thus, in these embodiments, the present invention is directed to a method for determining the ability of a candidate substance to inhibit the formation of the human Fc_{RI} complex, the method including generally the steps of:

10 (a) obtaining a composition comprising the human alpha, beta and gamma subunits of Fc_{RI} that are capable of complexing to form a functional and/or expressed receptor;

15 (b) admixing a candidate inhibitor substance with the composition; and

20 (c) determining the functional or expressed ability of the admixture.

An important aspect of the candidate substance screening assay hereof is the ability to prepare a composition of alpha, beta and gamma subunits in a relative purified form, for example, in a manner discussed herein. An aspect of the candidate substance screening assay is that without at least a relatively purified preparation, one will not be able to assay 25 specifically for Fc_{RI} inhibition, as opposed to the effects of the inhibition upon other substances in the extract which then might affect the receptor. In any event, the successful cloning and isolation of the beta subunit now allows for the first time the ability to 30 identify new compounds which can be used for inhibiting the Fc_{RI} in specific ways, thereby inhibiting the effects of the Fc_{RI} when bound to IgE.

The candidate screening assay is quite simple to set up and perform, and is related in many ways to the assays 35 discussed above for determining Fc_{RI} activity. After obtaining a relatively purified preparation of the alpha, beta and gamma subunits, one will desire to simply admix a candidate substance with the preparation, preferably under conditions which would allow the receptor to form

but for inclusion of an inhibitory substance. Thus, for example, one will typically desire to use cell activation assays as indirect measures of the presence of a functional receptor, or receptor expression, or both.

5 Accordingly, one will desire to measure or otherwise determine the activity of the relatively purified receptor in the absence of the assayed candidate substance in order to assess the relative inhibitory capability of the candidate substance.

10 In still further embodiments, the present invention is concerned with a method of inhibiting receptor formation and/or function which include subjecting the subunits to an effective concentration of a candidate substance identified in accordance with the candidate screening assay embodiments. This is, of course, an important aspect of the invention in that it is believed that by inhibiting the receptor one will be enabled to treat or prevent various aspects of allergic reactions. It is believed that the use of such inhibitors to block 20 the release of histamine by binding of IgE to Fc,RI and serve to treat or palliate the symptoms of an allergic response. Inhibitors may be useful by themselves or in conjunction with other therapies.

EXAMPLE 24

25 Identification and Use of Fc,RI Inhibitors

If the action of receptor of IgE is inhibited, the allergic reaction will not proceed. This inhibition may be either at the level of transcription, translation, or protein action. Interference with transcription would necessitate interference with mRNA formation on the DNA template. Preferably, interference with the translation would necessitate interfering with the synthesis of proteins on the mRNA template. Alternatively, the action of the receptor may itself be disrupted either by 30 destroying the structure of the receptor, prohibiting its formation, or binding the receptor or components thereof 35 irreversibly to inhibitors.

Specifically designed peptides which block the function of the receptor are extremely valuable in preventing and treating allergic diseases. Embodiments of these blockers (antagonists) include any substrate analogues or inhibitor, e.g., oligopeptides or their derivatives which contain the amino acid sequence of the IgE binding site. Methods for identifying suitable inhibitors from candidate substances are disclosed in Example 23.

EXAMPLE 25

10 Preparation of the Human β Polypeptide
by Recombinant Techniques

It is an additional object of the present invention to provide a ready means for producing the human beta subunit for use in detecting inhibitors, to develop 15 treatment modalities, to develop antibodies for detection of the subunit, and to develop inactive mutants of the human beta subunits, which may also be used to inhibit formation of the Fc γ RI. Such mutants may be introduced into transgenic animals, for example, to produce animals 20 useful for β assays.

An exemplary embodiment for preparing the beta subunit protein is to prepare a nucleic acid segment which includes a nucleic acid sequence capable of encoding the desired protein or polypeptide. This 25 segment may be that which encodes the entire subunit or only some portion of it, for example, the alpha or gamma binding domain of the subunit. The segment may be as small as that capable of triggering a positive signal with an antibody, thereby, identifying the presence of a 30 beta subunit. Segments functionally equivalent to those shown in Fig. 14, may also be selected depending on the desired polypeptide to be produced. Functional equivalence may be determined by testing whether the 35 segment can cause cell activation using techniques disclosed herein to detect inhibitors from among candidate substances.

The nucleic acid segment selected is transferred into an environment appropriate for expression of the segment as a polypeptide. This environment may be a vessel containing a mixture capable of inducing expression.

5 Alternatively, the segment may be transferred to a host cell by transformation, transfection via a recombinant expression vector, electroporation, or a "gene gun." The host cell may be selected from CHO cells, T cells, KU812 cells, P815 cells, or the like.

10 The recombinant expression vector will generally include a promoter. Embodiments of promoters are the $\alpha 4$ promoter, or any other suitable prokaryotic or eukaryotic promoters.

EXAMPLE 26

15 Antibodies Against the Proteins
of the Present Invention

In other embodiments, the invention concerns the preparation of antibodies to the beta subunit of Fc_{RI} and species derived therefrom, either recombinant or nonrecombinantly prepared.

20 Compositions which include monoclonal antibodies of the present invention may be prepared by first fusing spleen cells of a rodent with myeloma cells from the same rodent species, wherein the rodent providing the spleen cells have been immunized with the β subunit peptide, precursor, or related peptides. The rodent species utilized will generally be a mouse. Of course, where a beta subunits is prepared which incorporates structural variations over the ones disclosed herein, it will likely 25 be able to successfully employ a hybridoma system according to the species of interest.

30 In addition, the present invention provides a method for isolating beta subunits from other species which may be found antigenically cross-reactive with that of the 35 human or rodent subunit. This method includes preparing an immunoabsorbent material having attached thereto an antibody to the subunit. Numerous immunoabsorbent

materials are known to those skilled in the art and include, for example, Affi-Gel, Cn-Sepharose, protein A-Sepharose, and numerous other well known immunoabsorbent techniques. All such techniques of the immuno cross-reactive species (for a more complete listing, see Monoclonal Hybridoma Antibodies: Techniques and Applications, John G. Hurrell, ed. CRC Press, 1982, incorporated herein by reference).

Materials and Methods

10 Screening of cDNA and genomic libraries

The human basophil cDNA library and the human leukocytes genomic library have been described before and are available (Kuster, 1990). The human lung cDNA library (Miller, 1989) and a human skin cDNA library were provided by L.B. Schwartz (Medical College of Virginia, Richmond).

The following probes were prepared for screening the various libraries: The EcoRI-EcoRV fragment of rat β (Kinet, 1988) and the EcoRI fragment of mouse β (Ra, 1989), both of which contain the entire coding sequence of β and part of the 3' untranslated region. Fragments of the coding region of rat β cDNA (bp 1-304) and mouse β cDNA (bp 433-708) were made by polymerase chain reaction (PCR). Multiple oligonucleotides corresponding to various regions of rat, mouse and human β were synthesized on a model 380A automated DNA synthesizer (Applied Biosystems, Foster City, CA). All double stranded DNA probes were radiolabeled by random primer labeling and the oligonucleotides by end labeling as described elsewhere (Davis, 1986).

Hybridization and washing conditions and procedures for plaque purification subcloning, sequencing and DNA analysis were as described previously (Kuster, 1990).

Southern blot analysis

Digestion of genomic DNA from five different individuals with BamH Bgl II, Eco RI, Hind III, Msp I and Pvu II and hybridization of these digests with a human cDNA probe (from start to stop codon) supports the existence of a unique gene (FIG. 18). In addition the lengths of the restriction fragments detected on the southern blot are entirely consistent with the lengths predicted from the sequence of the gene. Three BamHI sites (nucleotide 156, 6908, 9250) are presenting the gene. As expected only one fragment (156-9250) is seen here because the other fragments should not hybridize with the cDNA probe. The two predicted Bgl II fragments (+334 to +1766 and +1766 to +7419) and the two predicted Hind III fragments (-454 to +2724 and +2724 to 100042) are readily detected. The results obtained after EcoRI and PvuII digestions are consistent the fact that none of these sites are found in the sequence of the gene. Finally the pattern observed after Msp I digestion is also consistent with predicted fragments of 2067 bp, 3870 bp and a larger 5' fragment extending from nucleotide 3622 to an undetermined Mspl site upstream of the gene.

cDNA synthesis by using the Polymerase Chain Reaction (PCR)

Basophils from 240ml of blood were purified by double Percoll gradients as previously described (Warner, 1987) and basophil RNA extracted by the guanidium isothiocyanate method (Davis, 1986). Two µg of total RNA were reverse transcribed with Superscript reverse transcriptase using a random 9-mer primer as recommended by the manufacturer (Bethesda Research Laboratories, Gaithersburg MD). One twentieth of the reaction product was amplified using the following primers: a 23-mer complementary to nucleotide -2 to +21 of the human β coding sequence and as backward primer a degenerated 21-mer of the mouse and rat β sequences starting 32 nucleotides after the stop codon. Temperature cycles were as follows: 1 cycle of 2 min. 95° / 2 min. 94° / 5

min. 37° / 40 min. 72°, 4 cycles of 40 sec. 94° / 1 min. 37° / 4 min. 72°, and 36 cycles of 40 sec. 94° / 1 min. 50° / 4 min. 72° followed by a single 15 minute extension. One μ l of this reaction was reamplified 5 omitting cycles 2 to 5 and the amplification product subcloned into pCR1000 using the TA cloning kit (Invitrogen, San Diego, CA).

Direct sequencing of gene fragments obtained by PCR

Purified insert-containing phage DNA from the 10 leukocyte genomic library was linearized with NotI and 100ng amplified with primers flanking the region to be sequenced. DNA amplification was achieved using 40 of the following cycles: denaturation for 1 min. at 94°C, annealing or 2 min. at 45-50°C and extension for 3-6 min. 15 at 72°C. Subsequently 1 μ l of the amplified material was reamplified in three separate reactions (50 μ l). Under identical conditions omitting one of the 2 primers in order to generate single stranded DNA. The three reactions were pooled, applied to an Ultrafree MC 30.000 20 spin column (Millipore, Bedford MA), and washed four times before being evaporated by vacuum. The single stranded DNA was sequenced by using the omitted primer or an internal primer. The comparison of sequences obtained by this method or by sequencing non amplified fragments 25 being subcloned in pGEM vectors revealed no differences.

Sequencing the transcription start site

PCR was used to define the transcription start site. Procedures published elsewhere (Frohman, 1987) were modified as follows: 5 μ g RNA were reverse transcribed 30 as detailed above by using a primer corresponding to nucleotide +451 to 429 of the coding region. The resulting product was washed on a Centricon 100 column (Amicon, Beverly MA) and a poly-A tails were at both ends added using terminal transferase (Bethesda Research 35 Laboratories, Gaithersburg MD) as recommended by the manufacturer. One sixth of this reaction was amplified with the following 2 primers: a 33-mer consisting of the

M13 primer sequence followed by 17 T's and for the 3' end a primer derived from nucleotide 331 to 308 of the human β coding region sequence. Subsequently an internal amplification was performed exchanging the 3' primer for 5 one equivalent to nucleotide +189 to 169. Finally, single stranded DNA was produced for sequencing by using an oligonucleotide corresponding to nucleotide 54 to 33 as the only primer. For all PCR's the annealing temperature was 45°C, the extension time 3 min.

10 Analysis of the transcription start site by 5' extension

An end labeled oligonucleotide corresponding to the negative strand at nucleotide 54 to 33 after the start codon was hybridized overnight at 42°C to either 10 μ g total RNA from enriched basophils or 10 μ g tRNA, followed 15 by extension with Superscript reverse transcriptase (Bethesda Research Laboratories, Gaithersburg MD) at 45°C for 90 min. The primer-extended products were separated on a 5% polyacrylamide urea gel in parallel with the sequencing reactions of the genomic DNA.

20 Cell Line KU812

A new myeloid cell line (KU812) was established from a patient with blastic crisis of chronic myelogenous leukemia. His blasts were morphologically characteristic of immature basophils and basophil colonies were grown in 25 agar culture of the blood mononuclear cells. Suspension culture of his blood cells was continue for more than 2.5 years. The KU812 cells morphologically showed a fine reticular nuclei with nucleoli, and some of them contained metachromatic granules with toluidine blue (TB) 30 staining. These granules were positive for astra blue (AB) staining. Immunological marker studies revealed that there were no lymphoid characters except Fc receptors. The KU812 cells grew colonies in in vitro agar cultures, which were proved to be composed of 35 basophils by TB staining and AB staining. Cytogenetic analysis showed marked aneuploidy and was positive for the Philadelphia chromosome (Ph¹). The cell lysate was

proved to contain histamine. These data suggest that KU812 is a cell line from leukemic basophil precursors. This is the first human basophil cell line. KU812 is useful in clarifying the mechanism of basophilic differentiation of the stem cells.

5 (Kishi, Leuk, Res, 1985, a: 381-390).

Other methods

Northern and Genomic Southern blots were performed as described elsewhere (Davis, 1986). The various cDNAs were subcloned into the eukaryotic expression vector pCDL-SR(α) for the transfection studies (Takebe, 1988). COS-7 cells were transfected by the standard DEAE-Dextran method (Maniatis, 1982), except that a 3 minute incubation of the transfected cells in 10% DMSO in media

10 as added after the chloroquine treatment.

15 While the invention has been described with respect to certain specific embodiments, it will be appreciated that many modifications and changes may be made by those skilled in the art without departing from the spirit of the invention. It is intended, therefore, by the appended claims to cover all such modifications and changes as fall within the true spirit and scope of the invention.

SEQUENCE LISTING

(1) GENERAL INFORMATION:

- (i) APPLICANT: KINET, Jean-Pierre
- (ii) TITLE OF INVENTION: ISOLATION, CHARACTERIZATION, AND USE OF THE HUMAN B SUBUNIT OF THE HIC^u AFFINITY RECEPTOR FOR IMMUNOGLOBULIN
- (iii) NUMBER OF SEQUENCES: 34
- (iv) CORRESPONDENCE ADDRESS:
 - (A) ADDRESSEE: Foley & Lardner
 - (B) STREET: 1800 Diagonal Road, Suite 500
 - (C) CITY: Alexandria
 - (D) STATE: VA
 - (E) COUNTRY: USA
 - (F) ZIP: 22313-0299
- (v) COMPUTER READABLE FORM:
 - (A) MEDIUM TYPE: Floppy disk
 - (B) COMPUTER: IBM PC compatible
 - (C) OPERATING SYSTEM: PC-DOS/MS-DOS
 - (D) SOFTWARE: PatentIn Release #1.0, Version #1.25
- (vi) CURRENT APPLICATION DATA:
 - (A) APPLICATION NUMBER: US 07/869,933
 - (B) FILING DATE: 16-APR-1992
 - (C) CLASSIFICATION:
- (viii) ATTORNEY/AGENT INFORMATION:
 - (A) NAME: BENT, Stephen A.
 - (B) REGISTRATION NUMBER: 29,768
 - (C) REFERENCE/DOCKET NUMBER: 40399/154 NIHD
- (ix) TELECOMMUNICATION INFORMATION:
 - (A) TELEPHONE: (703)836-9300
 - (B) TELEFAX: (703)683-4109
 - (C) TELEX: 899149

(2) INFORMATION FOR SEQ ID NO:1:

- (i) SEQUENCE CHARACTERISTICS:
 - (A) LENGTH: 30 base pairs
 - (B) TYPE: nucleic acid
 - (C) STRANDEDNESS: single
 - (D) TOPOLOGY: linear

(xi) SEQUENCE DESCRIPTION: SEQ ID NO:1:

AAGTACTGGC TATGATTTTT TATCCCATTG

30

(2) INFORMATION FOR SEQ ID NO:2:

- (i) SEQUENCE CHARACTERISTICS:
 - (A) LENGTH: 38 base pairs
 - (B) TYPE: nucleic acid
 - (C) STRANDEDNESS: single
 - (D) TOPOLOGY: linear

WHAT IS CLAIMED IS:

1. A nucleic acid sequence capable of coding for a polypeptide having an amino acid sequence corresponding to the human beta subunit of Fc_{RI}.
2. The nucleic acid sequence of claim 1 further defined as a DNA sequence.
3. The DNA sequence according to claim 2, wherein said DNA sequence corresponds to that shown in FIG. 14 (SEQ ID NO:31), or an allelic or species variation thereof.
4. The DNA sequence according to claim 2, wherein said DNA segment encodes the human amino acid sequence set forth in FIG. 19 (SEQ ID NO:32), or an allelic or species variation thereof.
5. A polypeptide having an amino acid sequence corresponding to the human beta subunit of Fc_{RI}, isolated from its natural environment.
6. The polypeptide according to claim 5, wherein said polypeptide has the human amino acid sequence set forth in FIG. 19 (SEQ ID NO:32), or an allelic or species variation thereof.
7. A recombinant DNA molecule comprising a vector and the DNA sequence according to claim 2 or 3.
8. A cell that contains the recombinant DNA molecule according to claim 7.
9. A method of producing a polypeptide having an amino acid sequence corresponding to the human beta subunit of Fc_{RI}, said method comprising culturing the cell according to claim 8 under conditions such that said

DNA molecule is expressed, and said polypeptide thereby produced.

10. The method of claim 9 further comprising isolating said polypeptide from the cell.

11. A method of expressing a complete and functional human Fc,RI receptor as characterized in mast cells comprising introducing into a host cell nucleic acid segments capable of encoding the human α , β , and γ subunits of Fc,RI and effecting expression of said segments under conditions such that said receptor is formed.

12. The method of claim 11 wherein the nucleic acid segments are DNA segments.

13. A nucleic acid segment capable of hybridization with a segment of the mRNA from which the human beta subunit is translated and, when so hybridized, capable of inhibiting said translation.

14. An antibody capable of binding to the beta subunit polypeptide of claim 5 or the amino acid sequence of claim 4 and neutralizing the Fc,RI-related functions of the subunit.

15. The antibody of claim 14 which is a monoclonal antibody.

16. A nucleic acid segment comprising a hybridizing segment of at least approximately 14 nucleotides which is capable of hybridizing to a nucleic acid segment capable of encoding for at least an amino acid sequence comprising the aggregating functions of a human beta subunit under stringent conditions.

17. An amino acid sequence capable of binding to the amino acid sequence of the human beta subunit and inhibiting the aggregating functions of the subunit.

18. The nucleic acid segment of claim 16 further defined as capable of hybridizing to a mRNA capable of transcribing at least a fragment of the β subunit.

19. A recombinant expression vector which comprises a nucleic acid sequence encoding the human β subunit and from which said subunit is capable of being expressed when the vector is in a host cell.

20. A recombinant expression vector comprising a nucleic acid sequence selected from one of the following claims: 1, 13, 16, and 29.

21. A cell transfected with the nucleic acid segments of claims 1, 13, 16, or 29.

22. The transfected cell of claim 21 wherein the cell prior to transfection was selected from the group comprising CHO, COS, KU812, P815, Jurkett, 2M2 and 2B4 cells.

23. A method for determining the ability of a candidate substance to inhibit the formation or function of the human Fc_{RI}, comprising:

- (a) conferring on a host cell the ability to express the α , β , and γ subunits of the human Fc_{RI};
- (b) combining the host cell after step (a) with the candidate inhibitor substance;
- (c) placing the combination in conditions suitable for expression of Fc_{RI};

- (d) performing on the host cell candidate inhibitor combination of step c an assay for cell expression or for cell activation of a type which requires a functional human Fc,RI; and
- (e) determining whether the candidate substance has inhibited cell activation or receptor expression.

24. The method of claim 23 wherein the host cell is selected from the group consisting of CHO cells, T cells, KU818 and P815 cells, and the cell activation assay comprises measuring the phosphorylation of the Fc,RI receptor or of PLC- γ (phospholipase c- γ) by P^{32} label uptake.

25. The method of claim 23 wherein the host cell is selected from the group consisting of T cells, KU812 cells and P815 cells, and the cell activation assay comprises measuring calcium uptake response.

26. The method of claim 23 wherein the host cell is selected from the group consisting of T cells, KU812 cells and P815 cells, and the cell activation assay is the phosphatydil inositol metabolism.

27. A composition for the treatment of allergic diseases comprising human beta subunit inhibitor in a pharmaceutically acceptable carrier.

28. A method of treatment of allergic diseases in a human suffering therefrom, such method comprising administering to said human an amount of human beta subunit inhibitor effective to indirectly inhibit the binding of IgE to Fc,RI and to inhibit the aggregation function of the receptor or the signal transducing function related to allergic response.

98

29. A nucleic acid sequence coding for the amino acid sequence of claim 17.

INTERNATIONAL SEARCH REPORT

International Application No

PCT/US 93/03419

I. CLASSIFICATION OF SUBJECT MATTER (if several classification symbols apply, indicate all)*

According to International Patent Classification (IPC) or to both National Classification and IPC

Int.C1. 5 C12N15/12;	C07K15/00;	C12N5/10;	C12P21/00
C12P21/08;	A61K37/02		

II. FIELDS SEARCHED

Minimum Documentation Searched⁷

Classification System	Classification Symbols		
Int.C1. 5	C12N ;	C07K	

Documentation Searched other than Minimum Documentation
to the Extent that such Documents are Included in the Fields Searched⁸

III. DOCUMENTS CONSIDERED TO BE RELEVANT⁹

Category ¹⁰	Citation of Document, ¹¹ with indication, where appropriate, of the relevant passages ¹²	Relevant to Claim No. ¹³
X	<p>DDBJ DATABASE ENTRY HSIGERB, ACCESSION NO. D10583; 25 February 1992, K. MAEKAWA ET AL.; 'Determination of the sequence coding for the beta subunit of the human high-affinity IgE receptor' *abstract* & FEBS LETTERS vol. 302, 1992, pages 161 - 165</p> <p style="text-align: center;">----</p> <p style="text-align: center;">-/-</p>	1-27,29

* Special categories of cited documents :¹⁰

- "A" document defining the general state of the art which is not considered to be of particular relevance
- "E" earlier document but published on or after the international filing date
- "L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)
- "O" document referring to an oral disclosure, use, exhibition or other means
- "P" document published prior to the international filing date but later than the priority date claimed

"T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention

"X" document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step

"Y" document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art

"&" document member of the same patent family

III. DOCUMENTS CONSIDERED TO BE RELEVANT (CONTINUED FROM THE SECOND SHEET)		
Category	Citation of Document, with indication, where appropriate, of the relevant passages	Relevant to Claim No.
X	<p>PROCEEDINGS OF THE NATIONAL ACADEMY OF SCIENCES USA vol. 85, 1988, pages 6483 - 6487 J.-P. KINET ET AL.; 'Isolation and characterization of cDNAs coding for the beta subunit of the high-affinity receptor for immunoglobulin E' cited in the application *abstract; page 6484, left-hand column, second full paragraph; page 6485*</p> <p>---</p>	14, 15
Y	<p>THE JOURNAL OF BIOLOGICAL CHEMISTRY vol. 265, 1990, pages 6448 - 6452 H. KÜSTER ET AL.; 'Characterization and expression of the gene for the human Fc receptor gamma subunit' cited in the application *abstract; introduction; Table 1*</p> <p>---</p>	11, 12, 23
Y	<p>THE JOURNAL OF BIOLOGICAL CHEMISTRY vol. 266, 1991, pages 22613 - 22620 G. ALBER ET AL.; 'Structure-function relationships in the mast cell high affinity receptor for IgE' *abstract; results*</p> <p>---</p>	11, 12, 23
Y	<p>WO,A,9 004 640 (THE UNITED STATES OF AMERICA) 3 May 1990 *page 8, line 26 - page 12, line 27; page 17, line 10 - page 19, line 1; claims*</p> <p>---</p>	11, 12, 23
P, X	<p>THE JOURNAL OF BIOLOGICAL CHEMISTRY vol. 267, 1992, pages 12782 - 12787 H. KÜSTER ET AL.; 'The gene and cDNA for the human high affinity immunoglobulin E receptor beta chain and expression of the complete human receptor' *whole document*</p> <p>---</p>	1-27, 29
P, X	<p>FEBS LETTERS vol. 302, 1992, pages 161 - 165 K. MAEKAWA ET AL.; 'Determination of the sequence coding for the beta subunit of the human high-affinity IgE receptor' *abstract; Figure 4*</p> <p>-----</p>	1-27, 29

ANNEX TO THE INTERNATIONAL SEARCH REPORT
ON INTERNATIONAL PATENT APPLICATION NO.

US 9303419
SA 73566

This annex lists the patent family members relating to the patent documents cited in the above-mentioned international search report. The members are as contained in the European Patent Office EDP file on The European Patent Office is in no way liable for these particulars which are merely given for the purpose of information. 26/08/93
